(54) Title: APPARATUS AND METHOD FOR CONTROLLED DELIVERY OF A GAS

(57) Abstract: Disclosed are apparatus for delivery of a gas, e.g., carbon dioxide and/or chlorine dioxide, and methods of its use and manufacture. The apparatus includes an envelope, and a sachet within the envelope that contains reactant, which generates a gas in the presence of an initiating agent, e.g., water. In another embodiment, the apparatus includes a barrier layer, a sachet layer disposed adjacent to the barrier layer, a reactant disposed between the barrier layer and the sachet layer that generates a gas in the presence of an initiating agent, and an envelope layer disposed adjacent to the sachet layer.

AQ

## APPARATUS AND METHOD FOR CONTROLLED DELIVERY OF A GAS

### Related Applications

This application is entitled to the benefit of earlier filed U.S. Provisional Patent Application Serial. Nos. 60/190,028, filed March 17, 2000, and 60/183,368, filed February 18, 2000, and 60/259,896, filed January 4, 2001, under 35 U.S.C. § 119(e), and copending U.S. Patent Application Serial No. 09/660,117, filed September 12, 2000, under 35 U.S.C. § 120, the entire disclosure of each of which are hereby incorporated by reference herein.

### Field of the Invention

The invention relates generally to apparatus and methods for delivery of a gas and more specifically to apparatus and methods for controlling the amount, rate and duration of gas delivery.

### Background of the Invention

The use of gas for retarding, controlling, killing or preventing microbiological contamination (*e.g.*, bacteria, fungi, viruses, mold spores, algae and protozoa); retarding, preventing, or controlling biochemical decomposition; controlling respiration, deodorizing and/or retarding and preventing chemotaxis to name a few, is known. Such gases include, but are not limited to, chlorine dioxide, sulfur dioxide, nitrogen dioxide, nitric oxide, nitrous oxide, carbon dioxide, hydrogen sulfide, hydrocyanic acid, and dichlorine monoxide. For example, the use and efficacy of chlorine dioxide is documented and discussed in various publications such as G. D. Simpson *et al.*, *A Focus on Chlorine Dioxide, An Ideal Biocide* (visited Feb. 5, 2000) <http://clo2.com/readings/waste/corrosion.html>, and K.K. Krause, DDS *et al.*, *The Effectiveness of Chlorine Dioxide in the Barrier System* (visited Feb. 5, 2000) <http://www.dentallogic.com/dentist/effects.htm>.

In particular, chlorine dioxide has been found to be useful as a disinfectant, antiseptic and sanitizer. It is used, *e.g.*, to disinfect drinking water and various water supplies. In addition, chlorine dioxide finds use as a bleaching agent for flour, fats and textiles. Chlorine dioxide also has shown great utility as an antiseptic for treating metal and plastic surfaces, as well as other substrates such as countertops, meat processing and packaging equipment, and dental and medical instruments and devices.

- 2 -

One disadvantage of the prior art methods for generating chlorine dioxide gas generally is that unsatisfactory levels of by-products or reactants remain as a residue. For example, in the case of chlorine dioxide gas, the byproduct chlorite leaves residues on food handling equipment and medical and dental surfaces. Human contact with such residues should be avoided or substantially minimized according to FDA and EPA regulations.

Another requirement in the food handling and related industries is the need for raw materials or ingredients that are safe to handle in the preparation of the disinfectant. The requirement is for the inclusion of reagents that are safe to use and, after generating chlorine dioxide, produce side products that are non-toxic and/or biodegradable.

Also, although it has great beneficial characteristics, chlorine dioxide can not be transported commercially as a concentrated gas for its use and instead has been generated at the site where it is used. Thus, an on-site gas generation plant typically is required to generate the gas that is then delivered to the fluid in which it will be used. Such apparatus takes up space and represents a significant added expense. Moreover, even when prior art apparatus do not require a separate gas generation component *e.g.*, those shown in European Patent Publication No. 0 571 228 for sulfur dioxide generation, such apparatus are still undesirable because controlling the amount of gas generated, the efficiency of the generation, and the duration of the gas generation has proven difficult, if not unsuccessful.

There exists a need for the controlled, on-site generation of gases, such as sulfur dioxide and chlorine dioxide, which can be produced safely, efficiently and economically, without the necessity for a separate generation plant or unwanted by-products. The present invention addresses these needs.

#### Summary of the Invention

A novel approach to the delivery of gas has now been discovered. The present invention uses a unique delivery system that controls the rate and efficiency of gas-producing reactions. Moreover, by using discreet amounts of reactant contained within a multi-layered apparatus, the skilled practitioner can now fabricate a gas delivery apparatus that is compact, cost-effective and safe. Furthermore, the present invention can be used for a variety of applications, including delivery of gas to air or water, for a variety of purposes including disinfection, deodorization, bleaching and sanitization.

In one aspect, the present invention features an apparatus for delivery of a gas. An exemplary embodiment of this apparatus generally includes an envelope, a sachet disposed

- 3 -

within the envelope, and a reactant disposed within the sachet that generates a gas in the presence of an initiating agent, wherein the envelope allows release of the gas from the envelope.

One currently preferred embodiment of the invention features an apparatus for delivery of a gas which includes a first reactant disposed within a first sachet, a second reactant disposed  
5 within a second sachet, a third sachet disposed about the first sachet and the second sachet, an envelope disposed about the third sachet, a frangible pouch disposed within the envelope adjacent to the third sachet, and an initiating agent disposed within the frangible pouch. In this embodiment, the first reactant and the second reactant generate a gas in the presence of the initiating agent, and the envelope allows release of the gas from the apparatus.

10 In a third exemplary embodiment, the apparatus for delivery of a gas includes an envelope, a partition disposed within the envelope defining a first volume and a second volume, a first reactant disposed in the first volume, and a second reactant disposed within the second volume. In this preferred embodiment, the first reactant and the second reactant generate a gas in the presence of an initiating agent, and the envelope allows entry of the initiating agent into the  
15 apparatus.

In another embodiment, the apparatus for delivery of a gas includes a sachet and a reactant disposed within the sachet that generates a gas in the presence of an initiating agent. In this embodiment, the sachet allows contact of the initiating agent with the reactant and release of the gas from the apparatus.

20 In another aspect, the present invention features a method of forming an apparatus for delivery of a gas including the steps of (a) providing a multi-layer structure comprising a reactant layer centrally disposed between two sachet layers, and two envelope layers disposed adjacent to the two sachet layers such that the two sachet layers are centrally disposed between the two envelope layers, and (b) stamping the multi-layer structure such that the two envelope layers  
25 form an envelope defined about its perimeter by the stamp, and the two sachet layers form a sachet defined about its perimeter by the stamp.

In yet another aspect, the present invention features a method of delivering gas including the steps of (a) providing an apparatus for delivery of a gas comprising: an envelope, a sachet disposed within the envelope, and a reactant disposed within the sachet that generates a gas in the  
30 presence of an initiating agent, wherein the envelope allows release of the gas from the envelope; and (b) disposing the apparatus in an environment that comprises an initiating agent. The

- 4 -

environment can be liquid and the initiating agent can be water. Alternatively, the environment can be gaseous and the initiating agent can be water vapor.

In yet another embodiment, the apparatus for delivery of a gas includes a barrier layer, a sachet layer disposed adjacent to the barrier layer, a reactant disposed between the barrier layer and the sachet layer that generates a gas in the presence of an initiating agent, and an envelope layer disposed adjacent to the sachet layer. In this embodiment, the envelope layer allows release of the gas from the apparatus.

In yet another embodiment, the apparatus for delivery of a gas includes a barrier layer, a sachet layer disposed adjacent to the barrier layer, and a reactant disposed between the barrier layer and the sachet layer that generates a gas in the presence of an initiating agent. In this embodiment, the sachet layer allows entry of the initiating agent into the apparatus.

In yet another aspect, the present invention features a method of delivering gas including the steps of (a) providing a multi-layer structure comprising a reactant layer centrally disposed between a sachet layer and a barrier layer, and an envelope layer disposed adjacent to the sachet layer, and (b) sealing the perimeter of the barrier layer, sachet layer and barrier layer such that the reactant is disposed in a volume defined by the sachet layer and the barrier layer.

In yet another aspect, the present invention features a method of delivering gas including the steps of (a) providing a multi-layer structure comprising a reactant layer centrally disposed between a sachet layer and a barrier layer, and (b) sealing the multi-layer structure such that the reactant is disposed in a volume defined by the sachet layer and the barrier layer.

In yet another aspect, the present invention features a method of delivering gas including the steps of (a) providing an apparatus for delivery of a gas comprising an envelope layer, a sachet layer disposed adjacent to the envelope layer, a barrier layer disposed adjacent to the sachet layer, and a reactant disposed in a volume defined by the sachet layer and the barrier layer; and (b) disposing the apparatus in an environment that comprises an initiating agent.

In short, the invention provides the art with a heretofore unappreciated method and apparatus for the controlled generation of a gas. Moreover, in accordance with the present teachings, the invention can also readily be applied to the generation of a liquid.

The invention will be understood further upon consideration of the following drawings, description and claims.

Description Of The Drawings

The invention is pointed out with particularity in the appended claims. The drawings are not necessarily to scale, emphasis instead generally being placed upon illustrating the principles of the invention. The advantages of the invention described above, as well as further advantages  
5 of the invention, can be better understood by reference to the description taken in conjunction with the accompanying drawings, in which:

#### Detailed Description Of The Invention

A novel approach to the delivery of gas has now been discovered. By using discrete amounts of reactant contained within a multi-layered apparatus, the skilled practitioner can now  
25 fabricate a gas delivery apparatus that is compact, cost-effective, and safe. The present invention can be used for a variety of applications, including delivery of gas to air or water, for a variety of purposes including disinfection, deodorization, bleaching and sanitization.

One advantage to this approach is that gas can be generated without the need for mechanical equipment, thus freeing up any space such mechanical equipment would require.  
30 Another advantage is that the reactants, which can be dangerous to handle directly, are isolated from contact with the user by the layers, which enclose the reactant.

- 7 -

Another advantage is that the apparatus of the present invention does not allow for the dilution of the reactant. Because the reactant remains concentrated within the sachet, less reactant is necessary to drive the reaction to completion and the reaction is more efficient than it would be if the reactants were diluted. Furthermore, because the reaction is driven to completion, unreacted reactant is minimized or eliminated. The reactant concentration also minimizes unwanted by-products.

Yet another advantage is that the apparatus is small and therefore can be easily and economically shipped and administered. Yet another advantage is that the apparatus can be manipulated to allow for either rapid or slow delivery of gas. Another advantage is that the apparatus can be designed to deliver gas to either a gas, *e.g.*, air, or a liquid, *e.g.*, water. Other advantages will be evident to the practitioner having ordinary skill in the art.

In order to more clearly and concisely describe the subject matter of the claims, the following definitions are intended to provide guidance as to the meaning of specific terms used in the following written description, examples and appended claims.

As used herein the term "sachet" means a closed receptacle for reactant. The sachet is "closed" in the sense that the reactants are substantially retained within the sachet and the sachet volume is substantially sealed around its perimeter. However, the material or materials used to construct the sachet are chosen to allow entry of the initiating agent and exit of the gas generated. The material or materials used to construct sachets are referred to herein as "sachet layers." Sachet layers typically are constructed from a planar material, such as, but not limited to, a polymeric sheet or film. Preferred materials for sachet layers are described in greater detail below. Relying upon the teaching disclosed herein, and the general knowledge in the art, the practitioner of ordinary skill will require only routine experimentation to identify one or more sachet layers and/or construct one or more sachets adapted for the purpose at hand.

As used herein the term "envelope" means a closed receptacle wherein the envelope volume is sealed substantially about its perimeter, which contains at least one sachet and allows release of the gas from the envelope. The material or materials used to construct envelopes are referred to herein as "envelope layers." Envelope layers typically comprise a planar material such as a sheet or film, including, but not limited to perforated films, non-perforated films and membranes. Preferred materials for envelope layers are described in greater detail below. Relying upon the teaching disclosed herein, and the general knowledge in the art, the practitioner

- 8 -

of ordinary skill will require only routine experimentation to identify one or more envelope layers and/or construct one or more envelopes adapted for the purpose at hand.

“Permeable layer,” as used herein, refers to a layer that permits passage of gas generated by an apparatus of the present invention. Permeable layers typically are constructed from polymeric materials. Sachet layers and envelope layers are permeable layers.

“Impermeable layer,” as used herein, refers to a layer that substantially prevents or hinders passage of initiating agent. As contemplated herein, the impermeable layer does not participate in the generation of gas in that it does not facilitate contact between initiating agent and reactant. Impermeable layers can be constructed from various materials, including polymeric material, glass, metal, metallized polymeric material and/or coated papers. Preferred materials for impermeable layers are described in greater detail below. As used herein, barrier layers are impermeable layers.

The skilled artisan will appreciate that what is considered to be an “impermeable layer” and what is considered to be a “permeable layer” is defined relative to the transmission rates of the respective layers used to construct apparatus of the present invention and the desired shelf life of the product. Relying upon the teaching disclosed herein, and the general knowledge in the art, the practitioner of ordinary skill will require only routine experimentation to identify and/or construct one or more impermeable layers and one or more permeable layers adapted for the purpose at hand.

As used herein “reactant” means a reactant or a mixture of reactants that generate gas in the presence of an initiating agent. For purposes of the present invention, initiating agent includes, but is not limited to, gaseous or liquid water. For example, for dry biocidal applications of the present invention, such as for the reduction of molds when shipping fruit, moisture in the atmosphere can be used as an initiating agent. The term “dry application” for the purposes of this application means at least an application where the apparatus of the present invention is not immersed in water or any other liquid. The term “wet application” for the purposes of the present invention means at least an application where the apparatus of the present invention is immersed in water, or other liquid, which can optionally include water. For wet biocidal applications, *i.e.*, when the apparatus of the present invention is immersed in water or any other aqueous medium, such as that used for disinfecting dental or food equipment, the water in which the apparatus is immersed can be used as the initiating agent. Alternatively, the initiating agent

- 9 -

can be included within the apparatus, *e.g.*, contained in a frangible pouch disposed within the apparatus.

Generation of a gas, *e.g.*, by acid activation, is well known in the art. For example, chlorine dioxide ( $\text{ClO}_2$ ) is generated from sodium chlorite and an acid, such as citric acid, in the presence of moisture as follows.

Specific examples of this reaction include the following.

Alternatively, chlorine dioxide can be produced by the reduction of a chlorate, *e.g.*, sodium chlorate or potassium chlorate, in the presence of an acid, *e.g.*, oxalic acid. Generally the reaction occurs as follows.

For example, reduction of sodium chlorate by acidification in the presence of oxalic acid to produce chlorine dioxide can proceed as follows.

Another example of generation of a gas by acid activation is the activation of a sulfite, *e.g.*, sodium bisulfite or potassium bisulfite, with an acid, *e.g.*, fumaric acid and/or potassium bitartrate, in the presence of moisture to form sulfur dioxide.

Yet another example is the acid activation of a carbonate, *e.g.*, calcium carbonate with an acid, *e.g.*, citric acid, to form carbon dioxide.

Other applications will be apparent to the skilled practitioner. For example, the generation of nitrogen dioxide by the acid activation of a nitrite, *e.g.*, sodium nitrite or potassium nitrite. Alternative routes for generation of a gas, *e.g.*, reduction of chlorates by sulfur dioxide (Mathieson Process), are well known in the art and can be utilized in accordance with the present invention.

The present invention can be used in a wide variety of applications. For example, chlorine dioxide can be used for the disinfection of water, *e.g.*, municipal water treatment: as a disinfectant for foods, beverages, fruits and vegetables; and for the cleaning and disinfection of

- 10 -

medical, dental and food equipment. Chlorine dioxide has been shown to be an effective disinfectant at concentrations as low as 0.2 mg/L. Chlorine dioxide is a desirable replacement for chlorine, the traditional water treatment chemical, because it has been found to inactivate microbes at lower levels and over a wider pH range. For example, chlorine dioxide can be used to reduce or eliminate biofilms because it penetrates the cell wall of naturally occurring, colony-building microorganisms and disrupts the proteins necessary for reproduction. Moreover, chlorine dioxide does not produce chlorinate by-products, *e.g.*, trihalomethanes. Moreover, it has been found to be active against pathogens that are resistant to chlorine. It can be used as a slimicide in paper or pulp machines, for wastewater treatment, and for industrial water treatment, *e.g.*, cooling or recycle streams. It can be used for odor control or as an aerial biocide and virucide. It can be used for the treatment of sulfides in the oil industry, for industrial cleaning, *e.g.*, circuit board cleansing, and for paper or tallow bleaching. Sulfur dioxide also has a variety of uses, such as a mold and fungus inhibitor for use in shipping and storing fruits and vegetables. Based on the teachings disclosed herein the practitioner of ordinary skill will appreciate the numerous other applications for which the present invention can be used and provides a heretofore unmet need.

The present invention relates to apparatus and methods for delivering biocidal-effective amounts of a gas such as chlorine dioxide. The apparatus and methods of the present invention achieve delivery of a desired amount of gas, at a desired rate, over a desired time period. This is accomplished by disposing suitable reactants in a defined and confined volume such that upon initiation, the reactants, initiating agent, products, and by-products are held within a desired concentration range. The amount, rate and duration of delivery can be manipulated by, *e.g.*, choice of sachet layers, sachet volume, reactant amount, reactant ratio, envelope layers, and envelope volume. Such manipulations can be exercised by the artisan using only routine experimentation in view of the teachings disclosed herein together with knowledge in the art.

Generally, the present invention also relates to an apparatus for delivery of a gas that includes reactant disposed in a volume defined by at least one permeable layer and at least one impermeable layer. The one or more permeable layers can include a sachet layer and/or an envelope layer, and allows release of the gas from the envelope. The one or more impermeable layers can include one or more barrier layer.

Figures 1A and 1B are a perspective view and a cross-sectional side view, respectively, of an embodiment of an apparatus 10 constructed in accordance with the present invention. In

- 11 -

general overview, apparatus 10 includes an envelope 20, a sachet 30 disposed within the envelope 10, and reactant 40 disposed within sachet 30 that generates a gas in the presence of an initiating agent, *e.g.*, water. Envelope 20 allows contact of the initiating agent with sachet 30 and release of the gas from envelope 20.

5       Apparatus 10 is particularly useful for the rapid release of a gas for wet applications *e.g.*, delivery of 5 to 50 mg chlorine dioxide gas per liter of water in 5 to 15 minutes. The function of the envelope is to control the influx of the initiating agent, while limiting the diffusion of the reactants from the sachet to the surrounding fluid, be it gaseous or liquid. The envelope also allows the gas to diffuse to the surrounding fluid, be it gaseous or liquid. By limiting  
10       transmission of the initiating agent into the apparatus, and limiting and/or preventing diffusion of the reactants out of the apparatus, the reactant remains concentrated and the pH of the reactive system is localized within the apparatus to optimize the conversion of reactant to gas. Additionally, intermediates and/or by-products of the reaction, *e.g.*, water, also can contribute to the efficiency and/or duration of the reaction by its affect on the equilibrium of the reactions.

15       The envelope preferably is constructed of a material that is durable and stable. Preferably, it also is capable of fusing to a like material upon the application of heat for construction purposes, *e.g.*, so that two pieces of such material can be fused about its perimeter to form the envelope. The envelope can be constructed of various materials, including polymeric material, such as perforated films, membranes and selective transmission films.

20       Preferably, the envelope is constructed of envelope layers having a water vapor transmission rate (WVTR) between about 50 g/m<sup>2</sup>/24 hrs and about 1,000 g/m<sup>2</sup>/24 hrs, more preferably, between about 200 g/m<sup>2</sup>/24 hrs and about 800 g/m<sup>2</sup>/24 hrs, and most preferably between about 400 g/m<sup>2</sup>/24 hrs and about 700 g/m<sup>2</sup>/24 hrs. The measurement of water vapor transmission rate is routine and well known in the art. Also, the envelope preferably is  
25       hydrophobic.

Perforated films suitable for the construction of the envelope in accordance with the present invention include, but are not limited to, polymeric material, *e.g.*, Cryovac® perforated films available from Sealed Air Corporation (Duncan, SC). One such film is a hydrophobic polypropylene copolymer film sold under the designation SM700 by Sealed Air Corporation and  
30       has 330 holes per square inch having a diameter of 0.4 mm, a 6.4% perforated area, a thickness of about 20 microns, and a water vapor transmission rate of 700 g/m<sup>2</sup>/24hrs. Another suitable film is a hydrophobic polypropylene copolymer film sold under the designation SM60 by Sealed

- 12 -

Air Corporation and has 8 holes per square inch having a diameter of 0.4 mm, a 0.2% perforated area and a water vapor transmission rate of  $65 \text{ g/m}^2/24\text{hrs}$ . The artisan can readily identify suitable equivalents of any of the foregoing by exercising routine experimentation.

Selective transmission films are films that are neither perforated nor porous, but instead transfer gases through the polymer structure of the film. Selective transmission films are multilayered or mixed polymer materials, where the layers and the polymers are chosen for controlled transmission of gases such as carbon dioxide and oxygen. Selective transmission films are preferred in dry applications because it allows the gas to diffuse out of the envelope, while retaining the initiating agent once released from a frangible pouch. Moreover, the selective transmission film increases the stability of the apparatus prior to its use because it does not easily allow ambient water to diffuse into the apparatus, which could prematurely initiate the reactants.

Generally, a film that has a high carbon dioxide transmission rate is preferred. While not wishing to be bound to any theory, it is thought that the carbon dioxide transmission rate approximates the chlorine dioxide transmission rate because chlorine dioxide and carbon dioxide are about the same size. Preferably, the selective transmissive film has a selective gas transmission rate of between about  $500 \text{ cc/m}^2/24\text{hrs}$  and about  $30,000 \text{ cc/m}^2/24\text{hrs}$  for  $\text{CO}_2$  and between about  $1,000 \text{ cc/m}^2/24\text{hrs}$  and about  $10,000 \text{ cc/m}^2/24\text{hrs}$  for  $\text{O}_2$ . More preferably, the envelope is constructed of a material having a selective gas transmission rate of between about  $1,000 \text{ cc/m}^2/24\text{hrs}$  and about  $25,000 \text{ cc/m}^2/24\text{hrs}$  for  $\text{CO}_2$  and between about  $2,000 \text{ cc/m}^2/24\text{hrs}$  and about  $10,000 \text{ cc/m}^2/24\text{hrs}$  for  $\text{O}_2$ . Most preferably, the envelope is constructed of a material having a selective gas transmission rate of between about  $5,000 \text{ cc/m}^2/24\text{hrs}$  and about  $25,000 \text{ cc/m}^2/24\text{hrs}$  for  $\text{CO}_2$  and between about  $3,000 \text{ cc/m}^2/24\text{hrs}$  and about  $10,000 \text{ cc/m}^2/24\text{hrs}$  for  $\text{O}_2$ . Measurement of selective gas transmission rate is routine and well known in the art. One suitable selective transmission film is a multilayered polymer film having a carbon dioxide transmission rate of  $21,000 \text{ cc/m}^2/24\text{hrs}$  and an oxygen transmission rate of  $7,000 \text{ cc/m}^2/24\text{hrs}$  sold under the trade designation PD-961 Cryovac® selective transmission film from Sealed Air Corporation (Duncan, SC).

Figure 6 is a graph depicting gas concentration versus time comparing various apparatus fabricated with and without an envelope. The square-shaped data points correspond to an apparatus with an envelope constructed with perforated film sold under the trade designation SM60 by Sealed Air Corporation (Duncan, SC). As described above, this perforated film has 8 holes per square inch having a diameter of 0.4 mm, a 0.2% perforated area and a water vapor

- 13 -

transmission rate of  $65 \text{ g/m}^2/24\text{hrs}$ . The diamond-shaped data points correspond to an apparatus without an envelope. Both apparatus contain 50 mg sodium chlorite and 200 mg citric acid. Both include a sachet constructed from an extruded polypropylene hydrophilic membrane having a 0.65 micron pore size, sold under the trade designation JOTD obtained from Millipore  
5 (Bedford, MA). For both apparatus, the sachet volume was about 5.5 times the volume of the reactants. Both apparatus were each immersed in 1 liter of water and the chlorine dioxide concentration measured every 5 minutes for an hour.

Figure 6 demonstrates that the inclusion of an envelope increases the reaction efficiency, and consequently, the amount of gas delivered for the same amount and ratio of reactant is  
10 greatly increased. In Figure 6, the apparatus delivers about 12.5 mg of chlorine dioxide gas compared to the approximately 4 mg delivered by the apparatus without an envelope. Thus, the apparatus with the envelope delivered more than 3 times the chlorine dioxide delivered by the apparatus without it, both apparatus having the same amount and ratio of reactant and the same sachet layer. Moreover, Figure 6 demonstrates the envelope increased the length of time in  
15 which gas was generated by about 25 minutes. Of course, there may be instances where having only a sachet, *i.e.*, no envelope, may be advantageous. For example, where the performance of the apparatus without an envelope is sufficient, having only a sachet may be preferred because production is simplified, as the step of constructing the envelope is eliminated, and also because material costs may be decreased by eliminating the need to provide envelope layers to construct  
20 the envelope.

Figure 7 is a graph depicting gas concentration versus time comparing exemplary apparatus fabricated with envelope materials having different water vapor transmission rates. The triangular-shaped data points correspond to an apparatus without an envelope. The square-shaped data points correspond to an apparatus with an envelope constructed from perforated film  
25 sold under the trade designation SM700 by Sealed Air Corporation (Duncan, SC) having 330 holes per square inch having a diameter of 0.4 mm, a 6.4% perforated area and a water vapor transmission rate (WVTR) of  $700 \text{ g/m}^2/24\text{hrs}$ . The diamond-shaped data points correspond to an apparatus with an envelope constructed with perforated film sold under the designation SM60 by Sealed Air Corporation (Duncan, SC) having 8 holes per square inch having a diameter of 0.4  
30 mm, a 0.2% perforated area and a water vapor transmission rate of  $65 \text{ g/m}^2/24\text{hrs}$ . All three apparatus contain the same reactant and amount and ratio of reactant as used for the apparatus in Figure 6. For all three apparatus, the sachet volume was about 5.5 times the volume of the

- 14 -

reactants. The reactants were enclosed sachets constructed from 0.65 micron pore size, hydrophobic, non-woven polypropylene material sold under the trade designation ANO6 by Millipore (Bedford, MA). These apparatus also were each immersed in 1 liter of water and the chlorine dioxide concentration measured every 5 minutes for an hour.

5 Figure 7 demonstrates the effect of the water vapor transmission rate of the envelope on the rate and efficiency of the reaction. In Figure 7, the apparatus having no envelope has a greater rate of reaction for about the first 15 minutes, but is less efficient than the apparatus with envelopes, delivering only about 12 mg of chlorine dioxide. The apparatus having envelopes exhibit greater efficiency and a longer rate of gas generation, which is proportional to the water  
10 vapor transmission rate (WVTR). The envelope with a water vapor transmission rate of 65  $\text{g/m}^2/24$  hrs has the greatest efficiency at about 55 minutes, generating about 22 mg of chlorine dioxide at a rate of about 5.5 mg of chlorine dioxide every 15 minutes. The envelope with a transmission rate of 700  $\text{g/m}^2/24$  hrs generates about 18 mg of chlorine dioxide in about 55 minutes at a rate of about 4.5 mg of chlorine dioxide every 15 minutes. Thus, for applications  
15 where it is desired to increase efficiency and to generate gas over an increased period of time, an envelope with a low vapor transmission rate is preferred. As mentioned above, however, there may be may be applications where having a less efficient apparatus may be advantageous, *e.g.*, decreased material and/or production costs.

By increasing or decreasing the water vapor transmission rate, the practitioner can control  
20 the rate and efficiency of the reaction to suit the application. For example, it has been found that an apparatus having a hydrophobic polypropylene envelope with a pore size of 0.1 micron, a 0.65 micron pore size hydrophilic polypropylene sachet, and reactants that include 500 mg sodium chlorite and 2000 mg citric acid, will generate 3.5 mg chlorine dioxide gas per hour for at least 30 hours.

25 It has been discovered that the use of a sachet can be used to limit the diffusion of the initiating agent into the sachet, and limit the diffusion of reactant and reactant by-products out of the sachet. As a consequence, the reactants are and remain concentrated within the sachet and the pH remains localized increasing the efficiency of the reaction. Various attributes of the sachet, such as pore size, bubble point, and hydrophobic and/or hydrophilic nature of the sachet  
30 membrane, can be manipulated to control the affect of the sachet on the reaction as is described below.

- 15 -

The sachet preferably is constructed of a material that is durable and stable. Preferably, it also is capable of fusing to a like material upon the application of heat or ultrasonics for construction purposes, *e.g.*, so that two pieces of such material can be fused about its perimeter to form the sachet.

5 Envelopes and sachets of the present invention can be sealed about their perimeter by any known method, such as heat sealing, ultrasonic sealing, radio frequency sealing, and sealing with adhesives. A preferred method of forming envelopes and sachets is to use an impulse sealer, which delivers a rapid and discreet thermal pulse to the layers. One impulse sealer suitable for use in accordance with the present invention is the 16" TISH400 Impulse Sealer available from  
10 TEW Electric Heating Equipment Corporation (Taiwan).

The sachet layers used to construct the sachet can be chosen to control the diffusion of the reactants out of the sachet, control the rate of gas release from the sachet and control the initiation of the reactants. For example, a hydrophilic sachet will increase the rate at which water and/or water vapor diffuses into the sachet, and the pore size and thickness of the sachet layer  
15 also will effect the passage of water, reactants and gas through the sachet layer.

The sachet can be constructed of various materials, including polymeric material or coated papers. It can be constructed from woven material, non-woven membrane, extruded membrane, or any other material with a controlled pore distribution having a mean pore size between about 0.01  $\mu\text{m}$  and about 50  $\mu\text{m}$ .

20 A woven material is any material woven from cotton, metal, polymer threads, metal threads or the like into a cloth or mesh. Extruded membranes, which include cast membranes, are preferred, and include 0.65 micron pore size, 230 to 260 micron thick, hydrophilic polypropylene sachet sold under the trade designation MPLC from Millipore (Bedford, MA), 0.65 micron pore size, extruded hydrophobic polypropylene material sold under the trade designation DHOP by  
25 Millipore (Bedford, MA). Also preferred is the cast membrane 3 micron pore Nylon 6,6 material sold under the trade designation BIODYNE A by Pall (Port Washington, NY). Non-woven membranes are membranes formed from materials such as cellulose or polymers. Other cast membranes include 0.45 pore, hydrophilic Nylon 6,6 membranes with a polypropylene backbone sold under the designation BA05 by Cuno Incorporated (Meriden, CT); 0.45 pore, hydrophilic  
30 polypropylene membrane available from 3M (City, State); and 0.45 pore size, 180 to 240 micron thick, hydrophilic Nylon 6,6 membranes sold under the designations 045ZY and 045ZN by Cuno Incorporated (Meriden, CT).

- 16 -

Also suitable for use in constructing the sachet are composite layers, including, but not limited to, starch/polymer composite layers. One currently preferred composite layer is a hydrophilic, 114  $\mu\text{m}$  thick, non-woven rice starch/polyethylene composite sold under the designation 60MDP-P by Mishima Paper Company, Limited (Japan). This layer is heat sealable and wets easily. Furthermore, this layer does not merely keep the reactants apart until initiation, but functions like other preferred sachet layers of the present invention in that it controls the rate diffusion of reactants out of the sachet, controls the rate of gas release from the sachet, and controls the initiation of the reactant so that the reactant remains concentrated within the sachet and the reaction is driven to completion.

Non-woven membranes can be formed, *e.g.*, by suspending the membrane material, *e.g.*, cellulose fibers, in a liquid over a porous web and then draining the liquid to form a membrane. Non-woven membranes typically have a relatively narrow and consistent pore size distribution as compared to woven materials. Consequently, the non-woven sachet generally allows less initiating agent into the sachet than the woven sachet having the same pore size because, generally the pore size distribution is narrower. A non-woven membrane suitable for use in accordance with the present invention is the 0.65 micron pore size, hydrophobic, non-woven polypropylene material sold under the trade designation ANO6 by Millipore (Bedford, MA).

In a preferred embodiment the sachet is constructed from a membrane having a pore size between about 0.01  $\mu\text{m}$  and about 50  $\mu\text{m}$ . More preferably, the pore size is between about 0.05  $\mu\text{m}$  and about 40  $\mu\text{m}$ , and most preferably, the pore size is between about 0.10  $\mu\text{m}$  and 30  $\mu\text{m}$ . The pore size of the sachet is measured by bubble point. Bubble point is a measurement well known in the art which approximates pore size from a measurement of the pressure necessary to drive a bubble of water through the sachet. Pore size affects the rate at which water and ions can diffuse through the sachet in both directions. A pore size preferably is chosen that allows entry of initiating agent into the sachet and, at the same time, retains the reactants within the sachet at a high concentration so that the reaction rate is increased and a high efficiency maintained. The artisan can readily identify suitable equivalents of any of the foregoing by exercising routine experimentation.

Preferably, the sachet is constructed from a membrane having a thickness between about 50 microns and 500 microns, more preferably between about 100 microns and 400 microns, and most preferably between about 150 microns and 300 microns.

- 17 -

In certain preferred embodiments, the material used to construct the sachet preferably has a bubble point between about 3 psi and about 100 psi, more preferably between about 5 psi and about 80 psi, and most preferably between about 10 psi and about 70 psi. As mentioned previously, the measurement of bubble point is routine and well known in the art and typically is supplied by suppliers of membranes, films, etc., however, the practitioner can readily make measurement.

Additionally, the sachet can be constructed from material that is hydrophobic and/or hydrophilic. It can also comprise a material having one or more hydrophilic zones and one or more hydrophobic zones. These zones can be created, *e.g.*, by printing a functional chemical group or polymer onto a surface of the sachet that is hydrophilic or hydrophobic or charged to create one or more hydrophilic or hydrophobic or charged zones. For example, a sulfonic acid group can be disposed on the surface of the polypropylene membrane, creating zones that are both hydrophilic and negatively charged ( $\text{R-SO}_2^-$ ). The membrane can then be washed with a dilute acid such that the ion exchange groups ( $\text{R-SO}_2^-$ ) bind the  $\text{H}^+$  ions. These  $\text{H}^+$  ions can later be released to supply  $\text{H}^+$  ions to acid activate reactant, *e.g.*, chlorite, as a replacement or supplement to acid reactant.

When the sachet is constructed of hydrophobic material, the hydrophobic material preferably has a flow time between about 10 sec/500ml and about 3,500 sec/500ml for 100% IPA at 14.2 psi. More preferably, the material has a flow time between about 60 sec/500ml and about 2,500 sec/500ml for 100% IPA at 14.2 psi, and most preferably, the material has a flow time between about 120 sec/500ml and about 1,500 sec/500ml for 100% IPA at 14.2 psi.

When the sachet is constructed of hydrophilic material as described above the hydrophilic material preferably has a flow time between about 5 sec/500 ml and about 800 sec/500 ml for 100% IPA at 14.2 psi. More preferably, the material has a flow time between about 20 sec/500ml and about 400 sec/500ml for 100% IPA at 14.2 psi, and most preferably, the material has a flow time between about 50 sec/500ml and about 300 sec/500ml for 100% IPA at 14.2 psi. Measurement of flow time is routine and well known in the art.

Yet another alternative embodiment uses a material to construct the sachet that has a first surface that is hydrophilic and a second surface that is hydrophobic. For example, a sachet can be constructed from such a material such that the hydrophilic surface is on the outside of the sachet and the hydrophobic surface is on the inside of the sachet. The exterior, hydrophilic surface aids the initiation of the reaction since water will readily wet a hydrophilic surface and

- 18 -

enter the sachet. However, once inside the sachet, the hydrophobic, interior surface limits water passage out of the sachet. This keeps the reactants concentrated within the sachet while allowing the gas to escape thus exploiting the advantages of the discoveries disclosed herein. One such material suitable for use in the present invention is a non-woven membrane 0.65 micron pore size diameter formed from a hydrophobic material, such as polypropylene, that has been

5 chemically functionalized with amines and carboxyl groups to produce a charge, hydrophilic surface.

The ratio of sachet volume to reactant volume also can be manipulated to control the concentration of the reactants, intermediates, by-products, etc. within the sachet. As discussed

10 previously, increasing the concentration of reactants generally increases reaction efficiency. Preferably the sachet volume is less than about 20 times the volume of reactant, more preferably less than about 10 times the volume of the reactant. Most preferably, it is less than 6 times the volume of the reactants. Smaller volumes are preferred in certain applications because when the ratio of sachet volume to reactant volume is small, water produced in the reaction increases the

15 pressure inside the sachet reducing the rate at which water can diffuse into the sachet, the water to reactant ratio remains constant and thus the rate of reaction remains constant. Preferably the volume of the envelope is from about 2 to about 6 times the volume of the sachet.

Figure 8 is a graph depicting gas concentration versus time comparing exemplary apparatus fabricated with and without a sachet. Specifically, Figure 8 depicts gas concentration versus time

20 comparing delivery of chlorine gas from reactant within a sachet versus reactant added directly to water, *i.e.*, with neither sachet nor envelope. The triangular-shaped data points indicate the rate of delivery of chlorine dioxide over time in 1 liter of water from a sachet material constructed from a 0.65 micron pore size, hydrophilic polypropylene membrane sold under the trade designation MPLC by Millipore (Bedford, CT). The sachet contained 200 mg citric acid and 50

25 mg of sodium chlorite. The sachet volume was about 5.5 times the volume of the reactants. The sachet was enclosed in an envelope constructed from perforated film sold under the trade designation SM700 by Sealed Air Corporation having 330 holes per square inch having a diameter of 0.4 mm, a 6.4% perforated area and a water vapor transmission rate of 700 g/m<sup>2</sup>/24hrs. The diamond-shaped data points indicate the rate of delivery of chlorine dioxide

30 over time when the same reactants in the same amounts were added to 1 liter of water directly, *i.e.*, with neither sachet nor envelope. The apparatus with the sachet delivered more than 10

- 19 -

times the chlorine dioxide than when the reactants were added directly to the water. As can be seen from Figure 8, the sachet increases the efficiency of the reaction.

Figure 9 is a graph depicting gas concentration versus time comparing an exemplary apparatus fabricated with extruded and non-woven sachets. The diamond-shaped data points indicate delivery of chlorine dioxide over time for the apparatus with a sachet constructed from 0.65 micron pore size, hydrophobic, non-woven polypropylene material sold under the trade designation ANO6 by Millipore (Bedford, MA). The square-shaped data points indicate delivery of chlorine dioxide over time for the apparatus with a sachet constructed from 0.65 micron pore size, extruded hydrophobic polypropylene material sold under the trade designation DHOP by Millipore (Bedford, MA). Both sachets contained 200 mg citric acid and 50 mg of sodium chlorite and the sachet volume was about 5.5 times the volume of the reactants. Neither apparatus included an envelope. The apparatus were each immersed in 1 liter of water and the chlorine dioxide gas concentration measured every five minutes for an hour.

As shown in Figure 9, both apparatus deliver chlorine dioxide at approximately the same rate for about the first 20 minutes. However, as the reactants become increasingly dilute in the extruded sachet relative to the non-woven sachet, the rate of the chlorine dioxide release diminishes. The efficiency of the reaction in the apparatus with the non-woven sachet is greater than that with the extruded sachet. The apparatus with the non-woven sachet also continue to generate chlorine dioxide gas at a rate of about 2mg every 5 minutes for about 15 minutes longer than the apparatus with the extruded sachet. As mentioned above, non-woven sachets generally have a relatively narrow pore size distribution, and without wishing to be bound to any theory, it is thought that this accounts for the greater efficiency and longer period of gas generation. Thus, Figure 9 provides a non-limiting illustration of how sachet material choice, and thus reactant concentration, can be exploited to sustain the rate of gas release and increase the efficiency.

Figure 10 is a graph depicting gas generation versus time comparing exemplary apparatus fabricated with sachets made of materials having hydrophobic and hydrophilic surfaces. The triangular-shaped data points correspond to an apparatus with a sachet constructed from 0.65 micron pore size, hydrophilic polypropylene sachet sold under the trade designation MPLC from Millipore (Bedford, MA). The diamond-shaped data points correspond to an apparatus with a sachet constructed from 0.65 micron pore size, extruded hydrophobic polypropylene material sold under the trade designation DHOP by Millipore (Bedford, MA). The square-shaped data points correspond to adding the reactant directly to the water. The reactant was 200 mg citric

- 20 -

acid and 50 mg of sodium chlorite and the sachet volume was about 5.5 times the volume of the reactants. Neither sachet was enclosed in an envelope. The apparatus and the reactant were each immersed in 1 liter of water and the chlorine dioxide gas concentration was measured every 5 minutes for an hour.

5        Figure 10 demonstrates that apparatus having a hydrophobic sachet results in a more efficient reaction that generates gas over a longer period of time than a hydrophilic sachet. In Figure 10, the apparatus with the hydrophobic sachet generated chlorine dioxide for about 30 minutes at about 2 mg every 5 minutes. In contrast, the apparatus with the hydrophilic sachet generated chlorine dioxide only for about 10 minutes at about 2 mg every 5 minutes. As  
10        disclosed above in connection with Figure 6, adding an envelope to either sachet will have the effect of increasing the efficiency of the reaction as well as increasing the length of time in which gas is generated.

      The reactant preferably comprises an aqueous soluble acid and a reactant that upon acid activation generates a gas. For example, for the generation of chlorine dioxide, preferably the  
15        reactant comprises an aqueous soluble acid and an aqueous soluble chlorite. For the generation of sulfur dioxide, preferably the reactant comprises an aqueous soluble acid and an aqueous soluble sulfite. Other examples of gas generating reactions are disclosed above.

      Any acid can be used as a reactant. However, weak acids are preferred, as they typically are safer to handle, produce less undesirable by-products, and are less reactive. Also,  
20        multifunctional acids are preferred. Multifunctional acids are acids that have more than one reactive site. For example, the difunctional acid, citric acid, is preferred. Preferably, the aqueous soluble acid is selected from the group consisting of phosphoric acid, fumaric acid, glycolic acid, acetic acid, ascorbic acid, oxalic acid, maleic acid, lactic acid, tartaric acid, citric acid and mixtures thereof. More preferably, the aqueous soluble acid is selected from the group  
25        consisting of ascorbic acid, oxalic acid, maleic acid, lactic acid, tartaric acid, citric acid and mixtures thereof. Most preferably, the aqueous soluble acid is ascorbic acid, oxalic acid, citric acid and mixtures thereof.

      For applications involving the generation of chlorine dioxide, preferably the aqueous soluble chlorite is selected from a group consisting of sodium chlorite and potassium chlorite and  
30        mixtures thereof. Preferably sodium chlorite is used.

      Preferably, the weight ratio of the aqueous soluble chlorite to the aqueous soluble acid is between about 1:2 to about 1:6, preferably from about 1:2.5 to about 1:5, most preferably from

- 21 -

about 1:3 to about 1:4.5. Preferably, a pH between about 1.5 to 5.5, more preferably a pH of about 2, is maintained by using an excess of acid. Because the reactants are concentrated within the sachet, less acid is needed to drive the reaction to completion and the pH remains low because the acid is concentrated. Furthermore, chlorite is consumed by acid and therefore the presence of chlorite is minimized.

Figure 11 is a graph depicting gas concentration versus time comparing apparatus fabricated with two different reactant ratios. The square-shaped data points correspond to an apparatus with a 1:4 ratio of citric acid to sodium chlorite (50 mg sodium chlorite and 200 mg of citric acid). The diamond-shaped data points correspond to an apparatus with a 1:1 ratio of citric acid to sodium chlorite (50 mg sodium chlorite and 50 mg citric acid). Both apparatus included a sachet constructed from 0.65 micron pore size, hydrophilic, polypropylene sachet sold under the trade designation MPLC from Millipore (Bedford, MA). The sachet volume was about 5.5 times the volume of the reactants. Both sachets were enclosed in an envelope constructed from perforated film sold under the trade designation SM700 by Sealed Air Corporation having 330 holes per square inch having a diameter of 0.4 mm, a 6.4% perforated area and a water vapor transmission rate of 700 g/m<sup>2</sup>/24hrs. These apparatus were immersed in 1 liter of water and the chlorine dioxide gas concentration measured every 5 minutes for an hour.

Figure 11 demonstrates that increasing the amount of citric acid relative to the amount of sodium chlorite increases the efficiency of the reaction, in part because the excess of acid drives the reaction to completion. The relationship of efficiency to reactant ratio is fairly predictable when the ratio of sodium chlorite to citric acid is between about 1:1 and about 1:6. Above about 1:6, there is little change in the efficiency of the reaction.

Ambient temperature also can affect the efficiency of the reaction. Generally, the hotter the temperature of the ambient fluid, *e.g.*, water or air, the more efficient the generation of gas.

Generally, however between the ranges of 10°C and 40°C, the efficiency improves as the temperature increases. The data used to generate Figures 6 through 11 and the Examples are from apparatus tested at from about 23 °C to about 25 °C. The sachet also can include various other ingredients that will be obvious to one skilled in the art, such as drying agents, stabilizers, and buffers to control the pH.

It also should be understood that the apparatus and methods of the present invention also are readily applicable to the delivery of more than one gas at one time. For example, the reactant

- 22 -

can include both a chlorite and at sulfite for the delivery of both chlorine dioxide and sulfur dioxide.

Figures 2A and 2B are a perspective view and a cross-sectional side view, respectively, of another embodiment of an apparatus 110 constructed in accordance with the present invention.

5 In general overview, apparatus 110 includes envelope 120 and two sachets 132, 134 disposed within the envelope 120. Sachets 132, 134 contain reactant 142, 144, respectively.

Apparatus 110 is particularly useful for the delivery of gas in wet applications. In such applications, reactant 142, 144 can be, *e.g.*, sodium chlorite and acid respectively, the sachet can be constructed from a material with a pore size large enough to allow diffusion of sodium  
10 chlorite and acid reactant out of the sachets, and the envelope can be chosen that does not allow the reactants to diffuse from the apparatus and regulates the release of gas from the apparatus so that the reaction remains efficient.

The envelope and sachet can be constructed from any of the material discussed in references to Figures 1A and 1B. Preferably, the envelope is a hydrophobic perforated film, such  
15 as the polypropylene copolymer film sold under the designation SM700 by Sealed Air Corporation (Duncan, SC) having 330 holes per square inch having a diameter of 0.4 mm, a 6.4% perforated area and a water vapor transmission rate of 700 g/m<sup>2</sup>/24hr. The envelope can also be constructed from 0.65 micron pore hydrophobic polypropylene membrane, such as that sold under the trade designation DHOP by Millipore (Bedford, MA).

20 For wet applications, most preferably the envelope is constructed from a cast membrane. Suitable cast membranes can be chosen to regulate the entry of initiating agent into the apparatus based on the thickness of the layer, the pore size and the hydrophobic and/or hydrophilic nature of the membrane. The thickness of the membrane is preferably between about 50 microns and about 500 microns, more preferably between about 100 microns and about 400 microns, and  
25 most preferably between about 150 microns to about 350 microns. The pore size preferably is between about 0.05 microns to about 5 microns, more preferably between about 0.2 microns and about 1.2 microns, most preferably between about 0.48 microns and 0.85 microns. A cast membrane suitable for use in accordance with the present invention is the 0.60 pore size, hydrophobic, polypropylene membrane having a thickness between about 250 microns and about  
30 300 microns sold under the designation 060P1 by Cuno Incorporated (Meriden, CT).

Sachets 132, 134 can be constructed from hydrophobic membrane and/or hydrophilic membrane. Preferred materials for sachets 132, 134 are described in connection with the

- 23 -

embodiment of Figures 1A and 1B. Preferably, the sachets 132, 134 are constructed from a hydrophilic material, *e.g.*, 0.65 micron pore size hydrophilic polypropylene membrane, such as that sold under the designation MPLC by Millipore (Bedford, MA), or extruded polypropylene hydrophilic membrane having a 0.65 micron pore size, sold under the trade designation JOTD  
5 obtained from Millipore (Bedford, MA), or a 114  $\mu\text{m}$  thick, non-woven rice starch polyethylene composite sold under the designation 60MDP-P by Mishima Paper Company, Limited (Japan). Also preferred are the 1.2 micron and 2 micron pore, hydrophilic Nylon 6,6 membranes sold under the designations 120ZY and 200ZY, respectively, by Cuno Incorporated (Meriden, CT), and the 1.2 and 2.0 micron pore size, hydrophilic polypropylene membranes sold under the  
10 designation MPLC by Millipore (Bedford, MA).

For wet applications, the pore size of the sachet membrane preferably is between about 0.01 microns to about 30 microns, more preferably between about 0.05 microns and about 20 microns, even more preferably between about 0.1 microns and about 10 microns, most preferably between about 1.2 microns and 5 microns. A pore size of between about 1.2 microns and 5  
15 microns is preferred in certain embodiments. Without wishing to be confined to any particular theory, it is believed that sachet layers with pore sized in the most preferred range allow rapid passage of the initiating agent into the reactant and diffusion of the reactant into the envelope. The envelope would then be chosen with a pore size that does not allow significant diffusion of the reactant out of the apparatus. The thickness of the sachet membrane preferably is between  
20 about 50 microns and about 500 microns, more preferably between about 100 microns and about 400 microns, and most preferably between about 150 microns to about 350 microns.

Reactant 142, 144 preferably includes an aqueous soluble acid and an aqueous chlorite that upon acid activation generates a gas. Preferably, these components are not mixed, but instead are separately contained in sachets 132, 134. It is preferred to separately contain the chlorite and the  
25 acid because this minimizes the likelihood of premature initiation, *e.g.*, during storage and shipment. Reactant 142, 144 can be liquid or solid, but is preferably solid.

Preferably the citric acid has a particle size of between about 15 microns and about 55 microns and is desiccated until about 6-8% of the initial weight is removed as excess moisture prior to incorporation into the apparatus of the present invention. Preferably the sodium chlorite  
30 has a particle size of between about 15 microns and about 55 microns and is desiccated to remove excess moisture prior to incorporation into the apparatus of the present invention.

- 24 -

In a preferred embodiment, the envelope 120 is hydrophobic and the sachets 132, 134 are hydrophilic. This preferred embodiment is particularly suitable for the delivery of gas in wet applications and has a slower rate of gas delivery than apparatus 10 of Figures 1A and 1B. For example, this embodiment can be used to deliver gas at low rates over long periods of time, *e.g.*, 20 mg of gas per hour over a 24 hour period. This embodiment also is preferred for applications where a high efficiency and concentration of gas is desired and it is possible to allow the apparatus a period of time to complete delivery, *e.g.*, 4 to 8 hours. This application also is preferred when working with relatively large amount of reactants that otherwise might begin reacting during construction and storage of the apparatus, *e.g.*, when constructing an apparatus having more than about 1 gram of sodium chlorite and 4 grams of citric acid. This embodiment is particularly useful for controlling and preventing biofilm contamination and as a disinfectant, antiseptic and sanitizer in applications where water is stored or conducted through conduits, *e.g.*, in swimming pools, water tanks, humidifiers, boat lines, beverage lines and the like.

Optionally, this embodiment could contain a second envelope (not shown) enclosing the first envelope 120. This second envelope might be useful, for example, in further regulating the introduction of the initiating agent through the envelope walls.

Optionally, this embodiment could contain a third sachet as depicted in Figure 19, which is a cross sectional side view of apparatus 1210 constructed in accordance with the present invention. Apparatus 1210 generally includes envelope 1220, and sachets 1232, 1234 and 1236, disposed within envelope 1220. Sachets 1232, 1234 and 1236 contain reactant 1242, 1244, and 1246, respectively. This embodiment is particularly useful, for example, when it is desired to separate acid and chlorite into separate sachets and the volume of one is significantly greater than the other, *e.g.*, the volume of acid is greater than the volume of chlorite. In this instance, one can separate the acid 1242 and 1246, into two sachets 1232, 1236 that are disposed on each side of the chlorite 1244 disposed within sachet 1234. This embodiment is preferred when using larger amounts of reactant, *e.g.*, one could construct an apparatus similar to that depicted in Figure 19, with 2 grams of sodium chlorite in one sachet, disposed between two sachets with 4-5 grams of citric acid in each. All other variables being equal, this embodiment is more efficient than embodiments having only two sachets when working with larger amounts of reactant. This embodiment also is easier to manufacture.

In a currently preferred embodiment, the reactant includes citric acid disposed in sachets 1232, 1236 and sodium chlorite is disposed in sachet 1234. The sachets 1232, 1234, 1236 are

- 25 -

constructed from 114  $\mu\text{m}$  thick, non-woven rice starch polyethylene composite sold under the designation 60MDP-P by Mishima Paper Company, Limited (Japan), and the envelopes are constructed from 0.60 pore size, hydrophobic polypropylene membrane having a thickness between about 250 microns and about 300 microns sold under the designation 060P1 by Cuno Incorporated (Meriden, CT).

This embodiment is particularly useful for controlling and preventing contamination and as a disinfectant, antiseptic and sanitizer in applications where water is stored or conducted through conduits, *e.g.*, in swimming pools, water tanks, humidifiers, boat lines, beverage lines and the like.

Figures 3A and 3B are a perspective view and a cross-sectional side view, respectively, of an apparatus 210 constructed in accordance with the present invention. Apparatus 210 includes first sachet 232, first reactant 242 disposed within first sachet 232, second sachet 234, second reactant 244 disposed within second sachet 234, third sachet 250 disposed about first sachet 232 and second sachet 234, and envelope 220 disposed about third sachet 250. Disposed within the envelope 220 adjacent to the third sachet 250 is frangible pouch 260, and initiating agent 264 disposed within frangible pouch 260.

Apparatus 210 is particularly useful for the delivery of gas in a dry application because initiating agent 264 is contained within the apparatus 210. In this embodiment, first reactant 242 and second reactant 244 generate a gas in the presence of initiating agent 264. For this to occur, frangible pouch 260 is ruptured, *e.g.*, by exerting pressure on frangible pouch 260 so that initiating agent 264 is delivered into first envelope 220. Third sachet 250 allows contact of initiating agent 264 with first sachet 232 and second sachet 242.

First sachet 232, second sachet 234, first reactant 242 and second reactant 244 are described above in reference to the embodiments shown in Figures 1A, 1B, 2A and 2B. In a currently preferred embodiment, first sachet 232 and second sachet 234 are constructed from a hydrophilic material having a pore size between about 3 microns and 5 microns. A suitable material is a 3 micron pore Nylon 6,6 material sold under the trade designation BIODYNE A by Pall (Port Washington, NY).

Third sachet 250 preferably is constructed using the materials described above in reference to the sachet material for the embodiments described for Figures 2A and 2B. The materials described above in reference to the embodiment described for Figures 1A and 1B can also be used. A suitable sachet layers is 0.65 micron pore hydrophobic polypropylene membrane, such

- 26 -

as that sold under the trade designation DHOP by Millipore (Bedford, MA). The third sachet limits the diffusion of reactant out of the third sachet and thus, it keeps the reactant concentrated within the third sachet and the pH localized. Preferably, the third sachet volume is less than 4 times that of the first reactant and the second reactant combined, and most preferably less than 2 times that of the first reactant and the second reactant combined.

Preferably, envelope 220 is constructed from a selective transmission film. Selective transmission films are described above in connection with Figures 1A and 1B. As discussed above, selective transmission films are preferred in dry applications because it allows the gas to diffuse out of the envelope, while retaining the initiating agent once released from the frangible pouch. Moreover, the selective transmission film increases the stability of the apparatus prior to its use because it does not easily allow ambient water to diffuse into the apparatus, which could prematurely initiate the reactants. Furthermore, keeping the reactant, *e.g.*, sodium chlorite and acid, separated into two sachets also can increase the stability of the apparatus because it retards initiation should initiating agent diffuse into the apparatus prior to rupturing the frangible pouch.

One suitable selective transmission film is a multilayered polymer film having a carbon dioxide transmission rate of 21,000 cc/m<sup>2</sup>/24hrs and an oxygen transmission rate of 7,000 cc/m<sup>2</sup>/24hrs sold under the trade designation PD-961 Cryovac® selective transmission film from Sealed Air Corporation (Duncan, SC).

Frangible pouch 260 can be constructed of any material that ruptures when pressure is applied to the envelope thus releasing the initiating agent inside it. Preferably, the frangible pouch is constructed from a multi-layer plastic, *e.g.*, polyolefin, envelope having a weak layer positioned near the sealing surface that will fail under pressure. Initiating agent 264 can be any agent that initiates a gas-generating reaction, *e.g.*, water. Preferably the initiating agent is water or an aqueous solution, but is not limited thereto.

The skilled practitioner will appreciate that the first reactant 242 and the second reactant 244 can be combined and disposed in a single sachet, *i.e.*, first sachet 232 and second sachet 234 can be combined into a single sachet (not shown). Moreover, the initiating agent 264 disposed in frangible pouch 260 can be disposed within the volume defined by the third sachet 250 (also not shown).

Figures 4A and 4B are a perspective view and a cross-sectional side view, respectively, of still yet another embodiment of an apparatus 310 constructed in accordance with the present invention. In general overview, apparatus 310 includes sachet 370 and partition 380 disposed

- 27 -

within sachet 370 defining first volume 382 and second volume 384 within sachet 370. Also shown is first reactant 342 disposed within first volume 382 and second reactant 344 disposed within second volume 384. In this embodiment, first reactant 342 and second reactant 344 generate a gas in the presence of an initiating agent, and sachet 370 allows entry of an initiating agent into apparatus 310.

Preferably, sachet 370 is constructed using a hydrophobic membrane to retard entry of the initiating agent into the apparatus. Preferably, partition 380 is constructed using hydrophilic membrane so that the initiating agent, once within the apparatus, will migrate to partition 380. These hydrophobic and hydrophilic membranes are described above for the embodiments depicted in Figures 1A, 1B, 2A, and 2B. Similarly first reactant 342 and second reactant 344 are described above for the embodiments depicted in Figures 1A, 1B, 2A, and 2B. If, for example, first reactant 342 consists of sodium chlorite and second reactant 344 consists of citric acid, reaction begins when an initiating agent reaches partition 380. In a preferred embodiment, sachet 370 is constructed from 0.65 micron pore hydrophobic polypropylene membrane, such as that sold under the trade designation DHOP by Millipore (Bedford, MA), and partition 380 is constructed from 0.65 micron pore hydrophilic polypropylene membrane, such as that sold under the designation MPLC by Millipore (Bedford, MA).

Optionally, the apparatus depicted in Figures 4A and 4B may further comprise an envelope (not shown) enclosing the sachet. This envelope can be constructed from any of the envelope materials described above for the embodiments depicted in Figures 1A, 1B, 2A and 2B.

Preferably, the envelope is a hydrophobic perforated film, such as the polypropylene copolymer film sold under the designation SM700 by Sealed Air Corporation (Duncan, SC) having 330 holes per square inch having a diameter of 0.4 mm, a 6.4% perforated area and a water vapor transmission rate of 700 g/m<sup>2</sup>/24hr. In a currently preferred embodiment, the envelope is constructed from a selective transmission film, such as the PD-961 Cryovac® selective transmission film from Sealed Air Corporation (Duncan, SC) disclosed above in connection with Figures 3A and 3B. Additionally, the apparatus can further comprise a frangible pouch, and initiating agent disposed within frangible pouch, disposed within the envelope.

Figures 5A and 5B are a perspective view and a cross-sectional side view, respectively, of still yet another embodiment of an apparatus 410 constructed in accordance with the present invention. In general overview, apparatus 410 includes sachet 430 and reactant 440 disposed

- 28 -

within sachet 430 that generates a gas in the presence of an initiating agent. Sachet 430 allows contact of the initiating agent with the reactant and release of the gas from the apparatus.

There may be instances where having only a sachet, *i.e.*, no envelope, may be preferred over embodiments that further include envelopes. For example, where the performance of the apparatus without an envelope is sufficient, this embodiment is preferred, because production is simplified as the step of constructing the envelope is eliminated, and also because material costs may be decreased by eliminating the need to provide envelope layers to construct the envelope.

Sachet materials can be constructed from the materials described above for the embodiments depicted in Figures 1A, 1B, 2A, and 2B. Preferably, the sachet is constructed using hydrophobic membrane so that the sachet limits the amount of water entering the sachet. Similarly, reactant 440 is described above for the embodiments depicted in Figures 1A, 1B, 2A, and 2B.

Figures 8, 9, and 10 depict concentration versus time for various apparatus that include a sachet but do not include envelopes. A currently preferred embodiment is an apparatus where the sachet is constructed from a 0.65 micron pore size, hydrophobic polypropylene membrane sold under the trade designation DHOP by Millipore (Bedford, MA). The diamond-shaped data points in Figures 9 and 10 depict the performance of an apparatus with a sachet and without an envelope constructed from this material.

In view of the collective teachings and guidance set forth herein, the practitioner can design, fabricate, test and use any number of embodiments of the present invention. All that is required is an ordinary level of skill in the art and some routine experimentation. For example, for a disinfection application, a practitioner initially should determine the volume to be disinfected using a gas-generating apparatus of the instant invention. Next, appreciating that the current standard for cold sterilization/disinfection is 5 mg/L chlorine dioxide, the practitioner should determine the quantity of chlorine dioxide that will be required to disinfect the desired volume.

From the volume of chlorine dioxide gas required, the amount and ratio of reactant necessary to generate this amount of chlorine dioxide can be calculated. Of course, if a practitioner wishes to increase or decrease the disinfecting concentration, then one can adjust the reactant quantities placed in a sachet. Representative data generated with varying ratios of reactants are depicted in Figure 11, for example. Variations in amounts generally are proportional, *e.g.*, doubling the amount of sodium chlorite will double the amount of chlorine

- 29 -

dioxide gas generated, if all other elements of the apparatus remain the same. Of course, the amount of gas generated can also be increased by envelope choice as described in connection with Figures 6 and 7.

Also, the practitioner should determine the time course of release of the disinfecting gas and choose sachet layers and envelope layers accordingly. For example, if a rapid release is desired, then reactants can be contained within a sachet fabricated from hydrophilic material; if a less rapid release is desired, then reactants can be contained in a hydrophobic material.

Representative data generated with hydrophobic and hydrophilic sachet material are depicted in Figure 10. Representative data generated with reactants housed in various embodiments of sachets and envelopes as taught by the present invention are depicted in Figures 6 through 11. The skilled artisan will appreciate that intermediate rates of release can be accomplished by mixing and matching different sachet layers and different envelope layers. Only routine experimentation is required.

Another aspect of the present invention features a method of forming an apparatus for delivery of a gas. This method includes the steps of: (a) providing a multi-layer structure comprising a reactant layer centrally disposed between two sachet layers, and two envelope layers disposed adjacent to the two sachet layers such that the two sachet layers are centrally disposed between the two envelope layers; and (b) stamping the multi-layer structure such that the two envelope layers form an envelope defined about its perimeter by the stamp, and the two sachet layers form a sachet defined about its perimeter by the stamp.

This method has many variations and embodiments. For example, a second reactant layer disposed between an additional two sachet layers can be included between the two envelope layers prior to step (a), so that upon stamping, the apparatus includes two sachets, each with its own reactant layer inside. Another variant adds the following steps to the method described above: (c) providing an initiating agent in a frangible pouch and a second two envelope layers, (d) stamping the second two envelope layers to form a second envelope defined about its perimeter by the stamp, such that the frangible pouch and the envelope formed in step (b) are disposed within the second envelope.

Stamping includes any method of forming an envelope from the envelope layers and a sachet from the sachet layers, *e.g.*, sealing the perimeter with a glue or other sealant, impulse sealing and heat sealing.

- 30 -

This method is advantageous because it allows the apparatus of the present invention to be manufactured quickly and inexpensively relative to assembling and forming each individual sachet and envelope separately.

5 In another aspect, the above method can be modified to construct an apparatus without an envelope. For example, the method can include the steps of: (a) providing a multi-layer structure comprising a reactant layer centrally disposed between two sachet layers; and (b) stamping the multi-layer structure such that the two sachet layers form a sachet defined about its perimeter by the stamp.

10 Yet another aspect of the present invention features a method of delivering gas. This method includes the steps of: (a) providing an apparatus for delivery of a gas comprising an envelope, a sachet disposed within the envelope, and a reactant disposed within the sachet that generates a gas in the presence of an initiating agent, wherein the envelope allows release of the gas from the envelope; and (b) disposing the apparatus in an environment that comprises an initiating agent.

15 This method has many variations and embodiments. For example, the environment can be liquid and the initiating agent can be water or the environment can be gaseous and the initiating agent can be water vapor. Preferably, the water vapor is that naturally diffused in the gaseous environment, *e.g.*, atmospheric water diffused in air at ambient temperature.

20 In another aspect, the above method can be modified to include the steps of: (a) providing an apparatus for delivery of a gas comprising a sachet and a reactant disposed within the sachet that generates a gas in the presence of an initiating agent; and (b) disposing the apparatus in an environment that comprises an initiating agent.

25 Optionally, to further increase stability of any of the apparatus of the present invention during storage and shipment, any desiccant, such as silica gel or molecular sieves, can be used to scavenge initiating agent prior to use of the apparatus.

#### Layered Apparatus

30 Figures 12A, 12B and 12C are an exploded view, a cross-sectional side view, and a perspective view, respectively, of an exemplary embodiment of an apparatus 510 constructed in accordance with the present invention. In general overview, apparatus 510 includes an envelope layer 520, a sachet layer 530 disposed adjacent to the envelope layer 520, a barrier layer 550 disposed adjacent to the sachet layer 530, and reactant 540 disposed in the volume defined by the sachet layer 530 and the barrier layer 550. The reactant 540 can generate a gas in the presence of

- 31 -

an initiating agent, *e.g.*, water. Sachet layer 530 and envelope layer 520, are permeable layers that allow passage of the initiating agent to the reactant 540 and release of the gas from the apparatus 510. Barrier layer 550 is formed to define a cavity 554 to receive reactant 540, and an edge 558 about its perimeter. The envelope layer 520 and sachet layer 530 are fused about their  
5 perimeter along the edge 558 of barrier layer 550. Apparatus 510 is particularly useful for the rapid release of a gas for wet applications.

Envelope layers are chosen to control the influx of the initiating agent, while limiting the diffusion of the reactants to the surrounding fluid, be it gaseous or liquid. The envelope layer also allows the gas generated by reactant to diffuse to the surrounding fluid, be it gaseous or  
10 liquid. By limiting transmission of the initiating agent into the apparatus, and limiting and/or preventing diffusion of the reactants out of the apparatus, the reactant remains concentrated and the pH of the reactive system is localized within the apparatus to optimize the conversion of reactant to gas. Additionally, intermediates and/or by-products of the reaction, *e.g.*, water, also can contribute to the efficiency and/or duration of the reaction by its affect on the equilibrium of  
15 the reactions.

Preferred envelope layers are described above for the embodiments depicted in Figures 1A, 1B, 2A, 2B, 3A, 3B, 4A, 4B, 5A and 5B. An envelope layer that is currently preferred for this embodiment is a hydrophobic polypropylene copolymer film sold under the designation SM700 by Sealed Air Corporation and has 330 holes per square inch having a diameter of 0.4 mm, a  
20 6.4% perforated area and a water vapor transmission rate of 700 g/m<sup>2</sup>/24hrs at 50% relative humidity. Also suitable is a hydrophobic polypropylene copolymer film sold under the trade designation SM570 that has 162 holes per square inch having a diameter of 0.4 mm mm, a 32% perforated area and a water vapor transmission rate of 570 g/m<sup>2</sup>/24hrs at 50% relative humidity and also is available from Sealed Air Corporation. Also suitable for use as an envelope layer is  
25 the polypropylene layer sold under the designation 060P1 by Cuno Incorporated (Meriden, CT).

The sachet layer can be used to limit the diffusion of the initiating agent into the volume defined by the sachet layer and the barrier layer, and limit the diffusion of reactant and any reaction by-products out of the volume defined by the sachet layer and the barrier layer. As a consequence, the reactant is and remains concentrated within the volume defined by the sachet  
30 layer and the barrier layer and the pH remains localized increasing the efficiency of the reaction. Various attributes of the sachet layer, such as pore size, bubble point, and hydrophobic and/or

- 32 -

hydrophilic nature of the sachet, can be manipulated to control the affect of the sachet layer on the reaction as is described above.

Preferred sachet layers are described above for the embodiments depicted in Figures 1A, 1B, 2A, 2B, 3A, 3B, 4A, 4B, 5A and 5B. Sachet layers that are currently preferred for this  
5 embodiment include an extruded, 0.65 micron pore size, hydrophilic polypropylene membrane sold under the trade designation MPLC from Millipore (Bedford, MA). Also suitable for use as sachet layers are the nylon 6,6 membrane layers sold under the designations 045ZN, 045ZY and 045ZL by Cuno Incorporated (Meriden, CT). The nylon 6,6 membrane layer sold under the trade designation 045ZY by Cuno Incorporated is currently preferred and has a thickness of between  
10 about 180 to about 240 microns, a pore size of about 0.45 microns, and a bubble point of about 24.1 psi.

The barrier layer preferably is constructed of a material that is durable and stable. Preferably, it is capable of being affixed to sachet layers and envelope layers for fabrication purposes, *e.g.*, so that the layers can be fused about their perimeters to form a defined volume.  
15 Preferably, the impermeable layer has a water vapor transmission rate (WVTR) of less than about 50 g/m<sup>2</sup>/24 hrs at 70% relative humidity. More preferably, the impermeable layer has a water vapor transmission rate (WVTR) of less than about 2 g/m<sup>2</sup>/24 hrs at 70% relative humidity. Most preferably, the impermeable layer has a water vapor transmission rate (WVTR) of less than about 0.5 g/m<sup>2</sup>/24 hrs at 70% relative humidity.

20 Barrier layers can be constructed of various materials, including metals, polymeric material and/or coated papers. Other suitable materials for forming barrier layers include, but are not limited to, polymeric layers constructed from, *e.g.*, polyethylene, polypropylene, polyester, styrene, including polystyrene, polyethylene terephthalate, polyethylene terephthalate glycol (PETG), polyvinyl chloride, polyvinylidene chloride, ethylvinyl alcohol, polyvinyl alcohol,  
25 including polyvinyl alcohol acetate, acrylobutylstyrene and/or polytetrafluoroethylene, polyacrylate and polyamide, including nylon. Also suitable are metallized layers, *e.g.*, any of the above polymeric layers that have been metallized. Also suitable are metallic foils, such as aluminum foils. Also suitable are non-woven layers such as layers made from spun-bonded olefin fibers, *e.g.*, layers available under the trade designation Tyvek® from DuPont Company  
30 (Wilmington, DE). Various other impermeable materials can be used to form the barrier film as well, such as glass or ceramics. In addition layers that are composites of the above layers and/or

- 33 -

laminates of the above layers, *e.g.*, paper/film/foil composites are also suitable for use as a barrier layer. One currently preferred impermeable layer is a 5 mil thick impermeable layer comprising a polyester exterior, a metallized biaxially oriented core, and a polyethylene interior sealing layer available from Sealed Air Corporation (Duncan, SC). This layer has a water vapor transmission  
5 rate of 0.01 g/100in<sup>2</sup>/24hrs at 70% relative humidity and 122°F. Another currently preferred impermeable layer is constructed from polyvinyl chloride. Yet another currently preferred impermeable layer is constructed from polyethylene terephthalate glycol (PETG).

The geometry and size of the barrier layer can be adapted to suit various parameters, including the amount and type of reactant, the desired surface area of the sachet layer and/or  
10 envelope layer, and attachments for the storage and use of the apparatus. In one currently preferred embodiment, the barrier layer forms a cavity to receive reactant. It is also preferable that the barrier layer is formed such that it includes an edge about its perimeter for forming a seal with the sachet layer and/or envelope layer and/or second barrier layer. It is also preferable that the barrier layer forms a cavity that, with the one or more permeable layers, defines a volume that  
15 is the same or only slightly larger than the volume of the reactants. That is, it is preferable to minimize reactant headspace in the apparatus of the present invention.

The barrier layer also can be formed into a shape such that the apparatus is easily inserted into or removed from various containers, such as a bottle or pouch. For example, it can be formed so that it can be inserted into a cap, such as a bottle cap or pouch cap, so that the cap can  
20 then be attached, *e.g.*, by a threaded seal, snap fit or pressure fit, to a receptacle for delivery of an initiating agent and/or receiving the generated gas. One such exemplary embodiment is described in greater detail in connection with Figures 16A and 16B below. The barrier layer also can be formed into various other geometries so that it can be otherwise affixed to a container, such as to a bottle. Two such exemplary embodiments are described in greater detail in  
25 connection with Figures 15 and 18 below.

The barrier layer can be formed into various geometries by various manufacturing methods known in the art, including but not limited to, horizontal form film seal, vertical form fill seal, blister pack, skin pack, injection molding, blow molding, thermoforming, cold forming fill seal, or mechanical forming. Of course, the barrier layer also may be flexible and not formed into any  
30 particular geometry, but sealed about its perimeter to the sachet about the reactant.

- 34 -

The envelope layer, sachet layer, and barrier layer of the present invention can be sealed about their perimeters by any known method, such as heat sealing, ultrasonic sealing, radio frequency sealing, impulse sealing, and sealing with adhesives. Preferably, the layers are fused with heat, by ultrasonic welding or by impulse sealing.

5        Reactant in general, preferred reactants, reactant ratios, and the like, are described above for the embodiments depicted in Figures 1A, 1B, 2A, 2B, 3A, 3B, 4A, 4B, 5A and 5B. Preferably, the reactant includes a stabilizer, such as activated hydrotalcite.

Optionally, in certain embodiments the reactant can further include a drying agent, or desiccant, to prevent premature initiation of the reactant. For example, desiccant can be added to  
10    the reactant to scavenge water vapor introduced during construction of the apparatus and/or shipping and storage of the apparatus, but in amounts small enough such that it would not prevent initiation when desired. Suitable desiccants include, for example, molecular sieves. Alternatively or additionally, desiccant can be separately contained in a permeable layer and located adjacent to or within the apparatus of the present invention to absorb or adsorb water  
15    vapor. One such exemplary embodiment is described in greater detail in connection with Figure 20 below.

The ratio of volume defined by the sachet layer and the barrier layer to reactant volume also can be manipulated to control the concentration of the reactants, intermediates, by-products, etc. within the volume defined by the sachet layer and the barrier layer. This relationship is  
20    described in above.

Figure 13 is a cross-sectional side view of another exemplary embodiment of apparatus 600 constructed in accordance with the present invention. In general overview, apparatus 600 includes an envelope layer 620, a sachet layer 630 disposed adjacent to the envelope layer 620, a barrier layer 650 disposed adjacent to the sachet layer 630, reactant 640 disposed in the volume  
25    defined by the sachet layer 630 and the barrier layer 650, and a second barrier layer 660 disposed adjacent to the envelope layer 620.

Sachet layer 630 and envelope layer 620, are permeable layers that allow passage of the initiating agent to the reactant 640 and release of the gas from the apparatus 600. Barrier layer 650 is an impermeable layer that defines a cuboid cavity 654 to receive reactant 640, and an edge  
30    658 about its perimeter where the barrier layer 650 is attached to the sachet layer 630 and the envelope layer 620.

- 35 -

The second barrier layer 660 is sealed about its perimeter to the envelope layer 620. Preferably, second barrier layer 660 is sealed to the envelope layer 620 by a peelable seal where the seal strength is such that the barrier layer 660 can be removed from the envelope layer 620 without disrupting either the seal between envelope layer 620 and sachet layer 630, or the seal  
5 between sachet layer 630 and barrier layer 650. Until the second barrier layer 660 is removed, it prevents initiation of the reactant 640 because it prevents passage of the initiating agent to the reactant 640. Second barrier film 660 can be used to prevent passage of the initiating agent into the apparatus when it is not in use, *e.g.*, during storage and shipping.

Apparatus 600 is particularly useful for applications where the apparatus 600 is likely to be  
10 stored and/or shipped in the presence of initiating agent, *e.g.*, water vapor in the surrounding air. Apparatus 600 also is particularly useful for applications where a relatively large amount of reactant is desired as cavity 654 is formed to accommodate a relatively large amount of reactant. The two barrier layers 650, 660 prevent initiation of the reactant 650 until the second barrier layer 660 is removed.

15 The envelope layer, sachet layer, and barrier layer can be constructed from any of the materials described above in connection with the embodiments depicted in Figures 1A, 1B, 2A, 2B, 3A, 3B, 4A, 4B, 5A, 5B, 12A, 12B and 12C. Reactant in general, preferred reactant, reactant ratios, reactant volume and the like, are described above in connection with the embodiments depicted in 1A, 1B, 2A, 2B, 3A, 3B, 4A, 4B, 5A, 5B, 12A, 12B and 12C.

20 Optional second barrier layer 660 can be constructed from any of the materials described above in connection with the barrier layer depicted in Figures 12A, 12B and 12C. Second barrier layer 660 also can be constructed from the same or different materials used to construct the barrier layer 650. Currently preferred second barrier layers include metal foil, nylon layers, polyvinylidene chloride layers, ethylvinyl alcohol layers and composites or laminate of these  
25 layers, such as a metallic foil/polyethylene layer laminate.

The second barrier layer can be sealed to the perimeter of the envelope layer, or sachet layer if no envelope layer is used, using any of the methods described above in connection with sealing the barrier, sachet layer and envelope layer of Figures 12A, 12B and 12C. Preferably, the second barrier layer is attached to the envelope layer by impulse sealing or heat sealing.  
30 Optionally, the second barrier layer also can include a device, such as a tab along its perimeter that facilitates its removal from the envelope layer without disrupting the other layers.

- 36 -

Figure 14 is a cross-sectional side view of another exemplary embodiment of apparatus 700 constructed in accordance with the present invention. In general overview, apparatus 700 includes an envelope layer 720, a sachet layer 730 disposed adjacent to the envelope layer 720, a barrier layer 750 disposed adjacent to the sachet layer 730, reactant 740 disposed in the volume defined by the sachet layer 730 and the barrier layer 750, and a second barrier layer 760 disposed adjacent to the envelope layer 720.

Sachet layer 730 and envelope layer 720, are permeable layers that allow passage of the initiating agent to the reactant 740 and release of the gas from the apparatus 700. Barrier layer 750 is an impermeable layer that forms a hemispheroid cavity 754 to receive reactant 740, and an edge 758 about its perimeter where the barrier layer 750 is attached to the sachet layer 730 and the envelope layer 720 by a heat or impulse seal.

The second barrier layer 760 also is sealed about its perimeter to the envelope layer 720 by a heat or impulse seal. Preferably, second barrier layer 760 is sealed to the envelope layer 720 so that it can be removed from the envelope layer 720 without disrupting the attachment of the envelope layer 720 to the sachet layer 730 and the sachet layer 730 to the barrier layer 750. Until the second barrier layer 760 is removed, it prevents initiation of the reactant 740 because it prevents passage of the initiating agent to the reactant 740. Second barrier film 760 can be used to prevent passage of the initiating agent into the apparatus when it is not in use, *e.g.*, during storage and shipping.

Apparatus 700 is particularly useful for applications where the apparatus 700 is likely to be stored and/or shipped in an environment that allows contact of the initiating agent with the apparatus. Apparatus 700 also is particularly useful for applications where it is desirable to utilize relatively small amounts of reactant to deliver gas to limited volumes of liquid. The two barrier layers 750, 760 prevent initiation of the reactant 740 until the second barrier layer 760 is removed.

The envelope layer, sachet layer, and barrier layer can be constructed from any of the materials described above in connection with Figures 1A, 1B, 2A, 2B, 3A, 3B, 4A, 4B, 5A, 5B, 12A, 12B, 12C and 13. Reactant in general, preferred reactants, reactant ratios, and the like, are described above in connection with Figures 1A, 1B, 2A, 2B, 3A, 3B, 4A, 4B, 5A, 5B, 12A, 12B, 12C and 13.

- 37 -

The second barrier layer can be constructed from any of the materials described above in connection with the barrier layers depicted in Figures 12A, 12B, 12C and 13. The second barrier layer can be sealed to the perimeter of the envelope layer, or sachet layer if no envelope layer is used, using any of the methods described above in connection with sealing the barrier, sachet layer and envelope layer of Figures 12A, 12B and 12C and 13. Preferably, it is heat or impulse sealed or sealed with an adhesive. Optionally, the second barrier layer also can include a device, such as a tab along its perimeter that facilitates its removal from the envelope layer without disrupting the other layers (not shown).

Figure 15 is a perspective view of still yet another exemplary embodiment of an apparatus 870 constructed in accordance with the present invention. In general overview, apparatus 870 includes a pouch 875 having a spout 880 and a cap 885, and apparatus 510 as described in connection with Figures 12A, 12B and 12C. The apparatus 510 can be affixed to a wall of pouch 875, *e.g.*, by adhesive or thermal bonding. Alternatively, it can be located within pouch 875 without being affixed thereto so that, *e.g.*, it can be removed and replaced after use.

Apparatus 870 is particularly useful for the release of gas into a desired amount of liquid, *e.g.*, water or air, so that a desired concentration of the gas in the liquid can be easily achieved. The amount of liquid can be defined by the volume of the pouch, pre-measured before addition of the pouch, or the pouch can include indicia located on the wall of the pouch to indicate various volumes that can be occupied by the liquid. The final concentration of the gas in the liquid can be controlled by choice of, *e.g.*, of reactant amount, reactant ratio, sachet layer, and envelope layer, as described in connection with Figures 1A, 1B, 2A, 2B, 3A, 3B, 4A, 4B, 5A, 5B, 12A, 12B, 12C, 13 and 14.

The pouch and cap can be constructed from any of the impermeable or permeable materials disclosed above in connection with Figures 12A, 12B, 12C and 13-14. Preferably, the pouch and cap are constructed from polypropylene, polyethylene, metal foil, nylon and/or composites or laminates of these layers such as a foil/polyethylene laminate. The pouch can be constructed from impermeable materials to avoid introduction of initiating agent into the pouch prior to the desired initiation of the reactant, *e.g.*, during shipping and storage. One such pouch material suitable for use in accordance with the present invention is constructed from a 5 mil thick impermeable layer comprising a polyester exterior, a metallized biaxially oriented core, and a polyethylene interior sealing layer. This layer has a water vapor transmission rate of 0.01

- 38 -

g/100in<sup>2</sup>/24 hours at 70% relative humidity and 122°F. Alternatively or additionally, the apparatus 510 can further include a second barrier film as described in Figures 13 and 14.

The apparatus 870 can be used by filling the pouch 875 with a liquid that includes initiating agent, attaching the cap 885 to the spout 880, and awaiting the generation of the desired quantity of gas by apparatus 510 into the liquid contained within the pouch 875. This embodiment can be useful for preparing solutions for removing biofilm and/or sanitizing plastic waterlines in dental, marine or aerospace applications. This embodiment can also be useful for preparing solutions for surface sanitation, infection control and the like. Alternatively, any other water reservoir, such as a rigid bottle may be used instead of the pouch.

Figures 16A and 16B are a perspective view and an enlarged cross-sectional side view of a portion, respectively, of yet another exemplary embodiment of an apparatus 972 constructed in accordance with the present invention. In general overview, the apparatus 972 includes a pouch 975, a spout 980, and a cap 985. The cap 985 includes a barrier layer 950, reactant 940, a sachet layer 930 and an envelope layer 920. The barrier layer 950 is formed to define a cavity to receive reactant 940 and also is formed to fit into cap wall 990. The barrier layer 950 is attached to the cap wall 990 by snap in pressure fit so that it stays in position and can be removed and replaced after generation and release of the gas. Cap wall 990 defines an interior thread 994 that matches exterior thread 996 defined by spout 980. Spout 980 further includes a second barrier film 995 that seals the opening defined by the spout 980.

Apparatus 972 is particularly useful for preparing solutions for removing biofilm and sanitizing plastic waterlines in dental, marine, beverage and aerospace applications. This embodiment also can be useful for preparing solutions for surface sanitation, infection control and the like. One advantage of this embodiment is that the barrier films 950, 995 prevent initiation of the reactant when not in use, e.g., during shipping and storage, by sealing the apparatus by threading the cap to the spout in an environment substantially free from initiating agent and not removing the cap until initiation is desired. When generation of gas is desired, the cap can then be removed from the spout, and the second barrier film removed from the spout. The pouch can then be filled with liquid in part or entirely, the cap replaced and the reaction initiated, such that gas is released and enters the pouch.

- 39 -

Apparatus 972 also is advantageous because the pouch need not be constructed from impermeable materials, because the second barrier film prevents initiation of reaction when not in use, *e.g.*, during storage and shipment.

The envelope layer, sachet layer, barrier layers, pouch and cap can be constructed from any of the materials are described in connection with Figures 1A, 1B, 2A, 2B, 3A, 3B, 4A, 4B, 5A, 5B, 12A, 12B, 12C, 13, 14 and 15. Reactant in general, preferred reactants, reactant ratios, and the like, also are described in connection with Figures 1A, 1B, 2A, 2B, 3A, 3B, 4A, 4B, 5A, 5B, 12A, 12B, 12C, 13, 14 and 15. The cap can be sealed by other means known in the art, *e.g.*, by a pressure fitting.

Optionally, a barrier film can be placed on the opening defined by the cap wall. Thus, the cap can be stored and shipped separately from the pouch. This can be advantageous, *e.g.*, in applications where the pouches can be reused, and thus material costs, storage space, storage costs, and shipping costs can be reduced. Alternatively, any other water reservoir, such as a rigid bottle may be used instead of the pouch depicted in Figures 16A and 16B.

Figures 17A and 17B are a cross-sectional side view and a perspective view, respectively, of still yet another exemplary embodiment of apparatus 1000 constructed in accordance with the present invention. In general overview, apparatus 1000 includes a sachet layer 1035, a barrier layer 1050 disposed adjacent to the sachet layer 1035, and reactant 1040 disposed in the volume defined by the sachet layer 1035 and the barrier layer 1050. Sachet layer 1035 is a permeable layer. Barrier layer 1050 is an impermeable layer and defines a cavity 1054 and an edge 1058 about its perimeter.

Apparatus 1000 is particularly useful for applications where the performance of the apparatus without an envelope layer is sufficient because production is simplified as the step of constructing the envelope layer is eliminated. In addition, eliminating the need to provide an envelope layer to construct the apparatus can decrease material costs.

The sachet layer and barrier layer can be constructed from any of the materials described in connection with Figures 1A, 1B, 2A, 2B, 3A, 3B, 4A, 4B, 5A, 5B, 12A, 12B, 12C, 13, 14, 15, 16A and 16B. Preferably, the sachet layer is constructed using a hydrophobic membrane so that the sachet layer limits the amount of water entering the apparatus. A currently preferred embodiment is an apparatus where the sachet layer is constructed from a 0.65 micron pore size, hydrophobic polypropylene membrane sold under the trade designation DHOP by Millipore

- 40 -

(Bedford, MA). Another currently preferred embodiment is an apparatus where the sachet layer is constructed from a polypropylene layer sold under the trade designation 060P1 by Cuno Incorporated (Meriden, CT).

Reactant in general, preferred reactants, reactant ratios, and the like, are described in connection with Figures 1A, 1B, 2A, 2B, 3A, 3B, 4A, 4B, 5A, 5B, 12A, 12B, 12C, 13, 14, 15, 16A and 16B.

Figure 18 is a cross-sectional side view of still yet another exemplary embodiment of an apparatus 1104 constructed in accordance with the present invention. In general overview, apparatus 1104 includes a tubular bottle 1106, a pump mechanism 1112 in threaded connection with the tubular bottle 1106 on a first end, a detachable portion 1124 in threaded connection with the tubular bottle 1106 on a second end, and insert 1132.

The bottle 1106 forms a spout 1108 that forms an exterior thread 1109 on the first end that attaches to the pump mechanism 1112 fixed in screw cap 1114 that forms a matching interior thread 1111. The bottle 1106 also defines an opening 1118 on the second end and exterior thread 1122 for attachment to the matching, interior thread 1126 defined by detachable portion 1124. Detachable portion 1124 also is formed to define a ridge 1128 about its interior perimeter that receives the insert 1132.

Insert 1132 includes a barrier layer 1150, reactant 1140, a sachet layer 1130, and an envelope layer 1120. The barrier layer 1150 is formed to snap into ridge 1128 and form a pressure fit so that it will remain in place during use and after use can be removed and replaced with another similarly configured insert. The barrier layer 1150 also is formed to define a cavity 1154 to receive reactant 1140 and an edge 1158 about its perimeter for attachment to the sachet layer 1130 and the envelope layer 1120. Optionally, insert 1132 can further include a second barrier layer adjacent to the envelope layer 1120 (not shown) as described in connection with Figures 13 and 14.

Pump mechanism 1112 includes tubular plunger 1133 on which pushbutton 1131 is mounted containing a spray nozzle 1134. Also shown are basic components of a typical pump, such as piston 1135, cylindrical chamber 1136, one-way valve 1137, collar 1138, and intake tube 1139. Alternate pump mechanisms are known in the art, such as the mechanisms described in U.S. Patent No. 4,077,549.

- 41 -

Apparatus 1104 is particularly useful for use in generating a desired concentration of gas in a liquid, *e.g.*, water, that can then be easily delivered to a desired location, *e.g.*, a countertop for disinfection, via a pump mechanism. The pump mechanism can be removed from the spout so that the volume defined by the tubular bottle and detachable portion can be filled, partially or  
5 entirely, with a liquid, *e.g.*, water. Detachable portion can be removed to attach or replace the insert 1132, so that bottle 1106, pump mechanism 1112, and detachable portion 1124 can be reused.

The envelope layer, sachet layer, and barrier layer can be constructed from any of the materials are described in connection with Figures 1A, 1B, 2A, 2B, 3A, 3B, 4A, 4B, 5A, 5B,  
10 12A, 12B, 12C, 13, 14, 15, 16A, 16B, 17A and 17B. Reactant in general, preferred reactants, reactant ratios, and the like, are described in connection with Figures 1A, 1B, 2A, 2B, 3A, 3B, 4A, 4B, 5A, 5B, 12A, 12B, 12C, 13, 14, 15, 16A, 16B, 17A and 17B.

The tubular bottle and the detachable portion can be constructed from any material described in connection with the pouch and cap described in Figures 15, 16A and 16B. The  
15 tubular bottle can be formed by any method known in the art, *e.g.*, blow molding or injection molding. Pump mechanism 1112 can be any pump mechanism known in the art. A wide variety of pump mechanisms are commercially available.

Figure 20 is a cross-sectional side view of another exemplary embodiment of apparatus 1310 constructed in accordance with the present invention. In general overview, apparatus 1310  
20 includes an envelope layer 1320, a sachet layer 1330 disposed adjacent to the envelope layer 1320, a barrier layer 1350 disposed adjacent to the sachet layer 1330, reactant 1340 disposed in the volume 1354 defined by the sachet layer 1330 and the barrier layer 1350, and desiccant 1341 disposed in the volume 1355 defined by the sachet layer 1330 and the barrier layer 1350.

Sachet layer 1330 and envelope layer 1320, are permeable layers that allow passage of the  
25 initiating agent to the reactant 1340 and release of the gas from the apparatus 1310. Barrier layer 1350 is an impermeable layer that forms cavities 1354, 1355 to receive reactant 1340 and desiccant 1341, respectively. The barrier layer 1350 is attached to the sachet layer 1330 and the envelope layer 1320 by a heat or impulse seal about the perimeter of the cavities 1354, 1355. Optionally a second barrier layer (not shown) can be sealed about its perimeter adjacent to the  
30 envelope layer 1320. Desiccant 1341 can be used to attract any ambient water vapor and/or

- 42 -

liquid water and thereby prevent or minimize passage of water vapor and/or liquid water to the reactant 1340 disposed in cavity 1354 during storage and shipping.

This embodiment is particularly useful for wet applications and is more resistant to premature initiation than, *e.g.*, the embodiment depicted in Figures 12A, 12B and 12C, due to the presence of the desiccant.

The envelope layer, sachet layer, barrier layer, and reactant can be any of those described in connection with the above Figures 1A, 1B, 2A, 2B, 3A, 3B, 4A, 4B, 5A, 5B, 12A, 12B, 12C, 13, 14, 15, 16A, 16B, 17A, 17B, 18 and 19. In a currently preferred embodiment, the envelope layer is a hydrophobic polypropylene copolymer film sold under the designation SM700 by Sealed Air Corporation and has 330 holes per square inch having a diameter of 0.4 mm, a 6.4% perforated area, a thickness of about 20 microns, and a water vapor transmission rate of 700 g/m<sup>2</sup>/24hrs, the sachet layer is extruded, 0.65 micron pore size, hydrophilic polypropylene membrane sold under the trade designation MPLC from Millipore (Bedford, MA) or Nylon 6,6 membrane layer sold under the trade designation 045ZY by Cuno Incorporated having a thickness of between about 180 to about 240 microns, a pore size of about 0.45 microns, and a bubble point of about 24.1 psi, the barrier layer is a polyethylene terephthalate glycol (PETG) or polyvinyl chloride (PVC) layer, the reactant includes sodium chlorite and citric acid, and the desiccant comprises molecular sieves.

Apparatus 1310 can also be incorporated into a pouch like that depicted in Figure 15 to generate a desired concentration of gas, *e.g.*, chlorine dioxide, in water. This embodiment is particularly useful in wet applications, *e.g.*, for use in removing biofilm from dental equipment. One such apparatus was constructed and used to generate an aqueous solution containing 50 parts per million chlorine dioxide. It was then emptied into a dental equipment reservoir and allowed to run through the equipment, which was contaminated with biofilm, and stand overnight. In the morning, the dental equipment was flushed with water. This procedure was repeated the following two nights. The equipment was then tested for the presence of biofilm and the biofilm was diminished. Thereafter, rinsing the equipment once daily with a 5 parts per million solution was adequate to retard the growth of biofilm in the equipment.

In view of the collective teachings and guidance set forth herein, the practitioner can design, fabricate, test and use any number of embodiments of the present invention. All that is required is an ordinary level of skill in the art and some routine experimentation.

- 43 -

Another aspect of the present invention features a method of forming an apparatus for delivery of a gas. This method includes the steps of: (a) providing a multi-layer structure comprising a reactant layer centrally disposed between a sachet layer and a barrier layer, and an envelope layer disposed adjacent to the sachet layer; and (b) sealing the perimeter of the barrier layer, sachet layer and barrier layer such that the reactant is disposed in a volume defined by the sachet layer and the barrier layer.

This method has many variations and embodiments. For example, a second barrier layer can be disposed adjacent to the envelope layer opposite the sachet layer prior to step (a). Another example is that in step (b) the seal can be effected by adhesive and/or by stamping the multi-layer structure with a hot die to heat-seal the layers together.

Sealing includes any method of substantially sealing the envelope layer, the sachet layer and the barrier layer about their perimeters, *e.g.*, sealing the perimeter with a glue or other sealant, impulse sealing, ultrasonic sealing and heat sealing.

In a preferred embodiment, the apparatus is manufactured in an array for ease of manufacturing. This method includes: (a) providing a layer of impermeable material that has an array of cavities formed therein; (b) disposing reactant in the array of cavities; (c) disposing one or more permeable layer over the layer of impermeable material; (d) sealing the one or more permeable layers to the layer of impermeable material about the perimeter of each cavity; and (e) cutting the impermeable material and the one or more permeable materials about the perimeter of each cavity.

This method is advantageous because it allows the apparatus of the present invention to be manufactured quickly and inexpensively relative to assembling and forming each individual sachet and envelope separately and/or manually.

The impermeable material provided in step (a) can have an array of cavities formed therein, *e.g.*, by using a thermoforming process to form the array of cavities. Thermoform machines suitable for use in accordance with the present invention include those manufactured by Multivac (Kansas City, MO), Tiromat (Avon, MA) Robert Reiser & Co. (Canton, MA), and Ulma Packaging (Woodstock, GA). Other suitable methods for forming the array of cavities include vacuum forming, cold forming, mechanical forming, and blister or skin packing process. The reactant can be disposed in the array of cavities on an assembly line and the one or more permeable layers can be sequentially positioned over the impermeable material, *e.g.*, by

- 44 -

unwinding sheets of the one or more permeable layers over the impermeable layer on an assembly line. The one or more permeable layers can then be sealed to the impermeable material about the perimeter of each cavity using methods known in the art, *e.g.*, adhesives, heat sealing methods, ultrasonic sealing methods, radio frequency sealing methods or impulse sealing. The impermeable material and the one or more permeable materials can then be cut about the perimeter of each cavity using methods known in the art, *e.g.*, by using a die, to form an apparatus similar to those depicted in Figures 12A, 12B, 12C, 13-15, 16A, 16B, 17A, 17B, 18 and 20.

These apparatus can then be inserted into the spout of a pouch that has been otherwise sealed about its periphery. Alternatively, it can be inserted into a pouch that has not been sealed about its periphery and the periphery then sealed, *e.g.*, by using adhesive, heat sealing methods, ultrasonic sealing methods, radio frequency sealing methods or impulse sealing methods. Optionally, the apparatus can be attached to a wall of the pouch, *e.g.*, by using adhesive, heat sealing methods, ultrasonic sealing methods, radio frequency sealing methods or impulse sealing methods.

In another aspect, the above method can be modified to construct an apparatus without an envelope. For example, the method can include the steps of: (a) providing a multi-layer structure comprising a reactant layer centrally disposed between a sachet layer and a barrier layer; and (b) sealing the multi-layer structure such that the reactant is disposed in a volume defined by the sachet layer and the barrier layer

Yet another aspect of the present invention features a method of delivering gas. This method includes the steps of: (a) providing an apparatus for delivery of a gas comprising an envelope layer, a sachet layer disposed adjacent to the envelope layer, a barrier layer disposed adjacent to the sachet layer, and a reactant disposed in a volume defined by the sachet layer and the barrier layer; and (b) disposing the apparatus in an environment that comprises an initiating agent.

This method has many variations and embodiments. For example, the environment can be liquid and the initiating agent can be water or the environment can be gaseous and the initiating agent can be water vapor. The apparatus can further comprise a pouch that can be filled with a desired liquid to receive the gas generated.

- 45 -

Optionally, to further increase stability of any of the apparatus of the present invention during storage and shipment, any desiccant, such as silica gel or molecular sieves, can be incorporated within the apparatus to scavenge initiating agent prior to use of the apparatus.

The present invention is useful for fabrication of a gas delivery apparatus that is compact, cost-effective and safe. Furthermore, the present invention can be used for a variety of applications, including delivery of gas to air or water, for a variety of purposes including removal of biofilm, disinfection, deodorization, bleaching and sanitation.

As a general rule and without wishing to be confined to any theory, it is expected that the amount and rate of gas release exhibited by apparatus of the present invention will be influenced by the total surface area of the permeable layer adjacent to the reactant, but not by the geometry of the apparatus. That is, the various embodiments of the present invention are expected to release the same volume of gas at the same rate provided that the total surface area of the permeable layer adjacent to the reactant is about equal, all other variables being held constant.

Example 1: An Apparatus In Accordance With The Present Invention

A membrane sachet was constructed by impulse sealing the perimeter of two 3 cm x 3 cm sheets of 0.65 micron pore hydrophilic polypropylene membrane sold under the trade designation MPLC obtained from Millipore (Bedford, MA). The sheets were impulse sealed a 16" TISH400 Impulse Sealer available from TEW Electric Heating Equipment Corporation (Taiwan). This sachet was filled with 50 mg of sodium chlorite and 200 mg citric acid. The sachet was then placed into an envelope formed by impulse sealing the perimeter of a 4 cm x 6 cm perforated film. The perforated film used was a SM700 Cryovac® perforated film from Sealed Air Corporation (Duncan, SC). This assembly was then placed in a 1 liter plastic bag filled with water for 15 minutes. The chlorine dioxide concentration in the water was measured using a Beckman DU-520 UV-Vis Spectrophotometer set at a wavelength of 360λ at about 6 mg/L.

Comparative Example 2: Direct Addition Of Reactant To Water

50 mg of sodium chlorite and 200 mg citric acid were added to 1 liter of water. The solution was allowed to sit for 15 minutes. The chlorine dioxide concentration in the water was measured using a Beckman DU-520 UV-Vis Spectrophotometer set at a wavelength of 360λ at about 0.5 mg/L. Figures 8 and 10 depict gas generation over time for adding the same amount and ratio of reactants to water.

- 46 -

Example 3: An Apparatus Without An Envelope

An apparatus was constructed as described in Example 1, except that the envelope was not included. This assembly was then placed in a 1 liter plastic bag filled with water for 15 minutes. The chlorine dioxide concentration in the water was measured using a Beckman DU-520 UV-Vis Spectrophotometer set at a wavelength of 360 $\lambda$  at about 5.5 mg/L. Such an apparatus and  
5 exemplary use of the same are depicted in Figure 10.

Example 4: An Apparatus Having Two Sachets

Two sachets were constructed by impulse sealing the perimeter of four 3 cm x 3 cm sheets of 0.65 micron pore hydrophilic polypropylene membrane sold under the trade designation  
10 MPLC obtained from Millipore (Bedford, MA). The first sachet was filled with 400 mg of sodium chlorite and the second sachet was filled with 1200 mg citric acid. Both sachets were then enclosed in an envelope formed by impulse sealing the perimeter of a 4 cm x 6 cm SM700 film obtained from Sealed Air Corporation having 330 holes per square inch having a diameter of 0.4 mm, a 6.4% perforated area and a water vapor transmission rate of 700 g/m<sup>2</sup>/24hr. This  
15 apparatus was then placed in a 1 liter plastic bag filled with water and let stand for 180 minutes. The chlorine dioxide concentration was measured using a Beckman DU-520 UV-Vis Spectrophotometer set at a wavelength of 360 $\lambda$  100 mg/L.

Example 5: An Apparatus Having Three SachetsAnd A Frangible Pouch Containing An Initiating Agent

Two sachets were constructed in accordance with Example 4 except that the sachets were constructed from 3 micron pore nylon 6,6 material sold under the trade designation BIODYNE A from Pall (Port Washington, NY). The first sachet was filled with 500 mg of sodium chlorite and the second sachet was filled with 2000 mg citric acid. Both sachets were then enclosed in a third sachet formed by impulse sealing the perimeter of a 5 cm x 7 cm 0.65 micron pore, hydrophobic  
25 polypropylene membrane sold under the trade designation DHOP by Millipore (Bedford, MA). A frangible pouch was constructed and filled with 5 ml of water. The frangible pouch and the third sachet (containing the first and second sachets and reactant) were then enclosed in an envelope formed by impulse sealing the perimeter of a 7 cm x 9 cm multilayered polymer film having a carbon dioxide transmission rate of 7,000 cc/m<sup>2</sup>/24hrs and an oxygen transmission rate  
30 of 21,000 cc/m<sup>2</sup>/24hrs sold under the trade designation PD-961 Cryovac® selective transmission film from Sealed Air Corporation (Duncan, SC). The frangible pouch was burst using manual pressure and this apparatus was then placed in a 1 liter plastic bag filled with water and let stand

- 47 -

for 180 minutes. The chlorine dioxide concentration in the water was measured using a Beckman DU-520 UV-Vis Spectrophotometer set at 360 $\lambda$  at 100 mg/L.

Example 6: An Apparatus Having An Envelope And A Bridge

A two-compartment membrane sachet was constructed by impulse sealing the perimeter of  
5 a 3 cm x 3 cm sheets of 0.65 micron pore hydrophilic polypropylene membrane, sold under the  
trade designation MPLC obtained from Millipore (Bedford, MA), between two 3 cm x 3 cm  
sheets of 0.65 micron pore hydrophobic polypropylene membrane sold under the trade  
designation DHOP by Millipore (Bedford, MA). Thus was formed a two compartment sachet  
having hydrophilic membrane on its outer walls and a divider of hydrophobic membrane for  
10 separating the reactant in each compartment. The first compartment of the sachet was filled with  
50 mg of sodium chlorite and the second compartment was filled with 200 mg citric acid. This  
multi-compartment sachet was then placed into an envelope formed by heat-sealing the perimeter  
of a 4 cm x 6 cm perforated film. The perforated film used was a SM700 Cryovac® perforated  
film from Sealed Air Corporation (Duncan, SC). This assembly was then placed in a 1 liter  
15 plastic bag filled with water for 15 minutes. The chlorine dioxide concentration in the water was  
measured using a Beckman DU-520 UV-Vis Spectrophotometer set at 360 $\lambda$  wavelength at about  
8 mg/L.

Example 7: An Apparatus For Generating Carbon Dioxide

A sachet was constructed by impulse sealing the perimeter of two 3 cm x 3 cm sheets of  
20 0.65 micron pore hydrophilic polypropylene membrane, sold under the trade designation MPLC  
obtained from Millipore (Bedford, MA). This sachet was filled with 50 mg of calcium carbonate  
and 100 mg citric acid. The sachet was then placed into an envelope formed by impulse sealing  
the perimeter of a 4 cm x 6 cm perforated film. The perforated film used was a SM700  
Cryovac® perforated film from Sealed Air Corporation (Duncan, SC). This assembly was then  
25 placed in a 1 liter plastic bag filled with water for 15 minutes. The carbon dioxide concentration  
in the water was measured using analyzed by ion chromatography at about 50 mg/L.

Example 8: An Apparatus For Long-Term Release

A sachet was constructed by impulse sealing the perimeter of two 4 cm x 6 cm sheets of  
0.65 micron pore hydrophilic polypropylene membrane, sold under the trade designation MPLC  
30 obtained from Millipore (Bedford, MA). This sachet was filled with 500 mg of sodium chlorite  
and 2000 mg citric acid. The sachet was then placed into an envelope formed by impulse sealing  
the perimeter of a 4 cm x 6 cm perforated film. The perforated film used was 0.1 micron pore

- 48 -

hydrophobic polypropylene membrane sold under the trade designation DHOP by Millipore (Bedford, MA). This apparatus was then placed in a 2 liter plastic bag filled with water. The chlorine dioxide concentration was measured every hour using a Beckman DU-520 UV-Vis Spectrophotometer set at a wavelength of 360 $\lambda$ . The apparatus generated about 3.5 mg per hour for 30 hours.

Example 9: An Exemplary Apparatus In Accordance With The Present Invention

An exemplary apparatus was constructed by sealing the perimeter of 6.1 cm diameter sheets of nylon 6,6 membrane layer sold under the trade designation 045ZY by Cuno Incorporated (Meriden, CT) and SM700 Cryovac® perforated film from Sealed Air Corporation (Duncan, SC) to a barrier layer filled with 240 mg of sodium chlorite, 60 mg of activated hydrotalcite, and 1,200 mg citric acid. The barrier layer was formed from polyvinyl chloride to define a barrier layer similar to barrier layer 50 depicted in Figures 12A, 12B and 12C. It had an outside a diameter of 6 cm and a 0.5 cm deep cavity formed therein having a 4.8 cm inside diameter. The layers were sealed about the edge of the barrier layer with an epoxy adhesive between the impermeable layer and the nylon 6,6 membrane layer, and between the nylon 6,6 membrane layer and the perforated film layer. The surface area of the nylon 6,6 layer adjacent to the reactant was about 18 cm<sup>2</sup> and the volume defined by the barrier layer and the nylon 6,6 layer was about 9 cm<sup>3</sup>. This assembly was attached by a snap fit to the interior wall of a polypropylene cap having a threaded fit to the spout of a 1 liter blow molded high density polyethylene plastic bottle. The bottle was filled with 1 liter of water, sealed with the cap, and turned upside down and left to stand. The chlorine dioxide concentration in the water was measured using a Hach DR890 Colorimeter and the standard Hach chlorine dioxide method at about 25 mg/L at 45 minutes and about 42 mg/L at 60 minutes. Hach Colorimeters are available from Hach Company (Loveland, CO). A similar apparatus and exemplary use of the same are depicted in Figures 16A and 16B.

Prospective Example 10: An Exemplary Apparatus with a Sachet and Envelope

A membrane sachet will be constructed by impulse sealing the perimeter of two 3 cm x 3 cm sheets of nylon 6,6 membrane layer sold under the trade designation 045ZY by Cuno Incorporated (Meriden, CT). The sheets are to be impulse sealed with a 16" TISH400 Impulse Sealer available from TEW Electric Heating Equipment Corporation (Taiwan). This sachet will be filled with 240 mg of sodium chlorite, 60 mg of activated hydrotalcite, and 1,200 mg citric

- 49 -

acid. The sachet will then be placed into an envelope formed by impulse sealing the perimeter of a 4 cm x 6 cm perforated film. The perforated film used will be a SM700 Cryovac® perforated film from Sealed Air Corporation (Duncan, SC). This assembly will then be placed in a 1 liter plastic bag filled with water for 15 minutes. The chlorine dioxide concentration in the water will be measured using a Hach DR890 Colorimeter and the standard Hach chlorine dioxide method. It is expected that readings of about 25 mg/L at 45 minutes and about 42 mg/L at 60 minutes will be obtained. Such an apparatus and exemplary use of the same are depicted in Figures 1A and 1B.

Prospective Example 11: An Exemplary Apparatus Including a Pouch and a Sealed Spout

An exemplary apparatus will be constructed as described in Example 9, except that this assembly will be fused to the interior wall of a one liter pouch. The pouch will be constructed from a 5 mil thick impermeable layer comprising a polyester exterior, a metallized biaxially oriented core, and a polyethylene interior sealing layer obtained from Sealed Air Corporation (Duncan, SC). This layer has a water vapor transmission rate of 0.01 g/100in<sup>2</sup>/24 hours at 70% relative humidity and 122°F. The spout will be constructed of injection molded polypropylene. The pouch will be sealed about its perimeter except for the opening defined by the spout. The one liter pouch will then be filled with water, capped, and allowed to stand. The chlorine dioxide concentration in the water will be measured as described in Example 9 and similar chlorine dioxide concentrations are expected at 45 and 60 minutes. Such an apparatus and exemplary use of the same are depicted in Figure 15.

Although generally the preferred embodiments of the invention have been shown and described, numerous variations and alternative embodiments will occur to those skilled in the art. Accordingly, it is intended that the invention be limited only in terms of the appended claims as the invention can be embodied in other specific forms.

- 50 -

CLAIMS

What is claimed is:

- 1        1.        An apparatus for delivery of a gas comprising:  
2        an envelope;  
3        a sachet disposed within the envelope; and  
4        a reactant disposed within the sachet that generates a gas in the presence of an initiating  
5        agent,  
6        wherein the envelope allows release of the gas from the envelope.
- 1        2.        The apparatus of claim 1 wherein the sachet comprises a material having a pore  
2        size between about 0.01  $\mu\text{m}$  and about 50  $\mu\text{m}$ .
- 1        3.        The apparatus of claim 1 wherein the sachet comprises a hydrophobic material.
- 1        4.        The apparatus of claim 1 wherein the sachet comprises a hydrophilic material.
- 1        5.        The apparatus of claim 1 wherein the sachet comprises a material having one or  
2        more hydrophilic zones and one or more hydrophobic zones.
- 1        6.        The apparatus of claim 5 wherein the one or more hydrophilic zones are created  
2        by printing an acid onto a surface of the sachet that is hydrophobic.
- 1        7.        The apparatus of claim 1 wherein the sachet comprises a material having a first  
2        surface that is hydrophilic and a second surface that is hydrophobic.
- 1        8.        The apparatus of claim 1 wherein sachet comprises a material having a bubble  
2        point between about 3 psi and about 100 psi.
- 1        9.        The apparatus of claim 3 wherein the sachet has a flow time between about 10  
2        sec/500ml and about 3,500 sec/500ml for 100% IPA at 14.2 psi.
- 1        10.       The apparatus of claim 4 wherein the sachet has a flow time between about 5  
2        Lmh/kPa and about 500 Lmh/kPa for 100% water at 14.2 psi.
- 1        11.       The apparatus of claim 1 wherein the envelope comprises a material having a  
2        water vapor transmission rate between about 50  $\text{g/m}^2/24 \text{ hrs}$  and about 1,000  $\text{g/m}^2/24 \text{ hrs}$ .

- 1        12.     The apparatus of claim 1 wherein the envelope comprises a material having a  
2        selective gas transmission rate of between about 500 cc/m<sup>2</sup>/24hrs and about 30,000 cc/m<sup>2</sup>/24hrs  
3        for CO<sub>2</sub>.
- 1        13.     The apparatus of claim 1 wherein the envelope comprises a material having a  
2        selective gas transmission rate of between about 1,000 cc/m<sup>2</sup>/24hrs and about 10,000 cc/m<sup>2</sup>/24hrs  
3        for O<sub>2</sub>.
- 1        14.     The apparatus of claim 1 wherein the reactant comprises an aqueous soluble acid  
2        and an aqueous soluble chlorite and the gas is chlorine dioxide.
- 1        15.     The apparatus of claim 14 wherein the aqueous soluble acid is selected from the  
2        group consisting of phosphoric acid, fumaric acid, glycolic acid, acetic acid, ascorbic acid, oxalic  
3        acid, maleic acid, lactic acid, tartaric acid, citric acid and mixtures thereof.
- 1        16.     The apparatus of claim 14 wherein the aqueous soluble chlorite is selected from a  
2        group consisting of sodium chlorite and potassium chlorite and mixtures thereof.
- 1        17.     The apparatus of claim 14 wherein the weight ratio of the aqueous soluble chlorite  
2        to the aqueous soluble acid is between about 1:2 to about 1:6.
- 1        18.     The apparatus of claim 1 further comprising a second sachet disposed within the  
2        envelope.
- 1        19.     The apparatus of claim 18 further comprising a third sachet disposed about the  
2        first sachet and the second sachet, the third sachet being disposed within the envelope.
- 1        20.     The apparatus of claim 18 further comprising a third sachet disposed within the  
2        envelope.
- 1        21.     The apparatus of claim 20 wherein the reactant comprises sodium chlorite  
2        disposed in the first sachet and the third sachet, and citric acid disposed in the second sachet.
- 1        22.     The apparatus of claim 21 wherein the first, second and third sachets are  
2        comprised of hydrophilic extruded membrane having a pore size between about 0.1 microns and  
3        about 10 microns and a thickness between about 100 microns and about 400 microns, and the

- 52 -

4 envelope comprises a hydrophobic membrane having a pore size between about 0.05 microns  
5 and about 5 microns and a thickness between about 100 microns and about 400 microns.

1 23. An apparatus for delivery of a gas comprising:  
2 a first reactant disposed within a first sachet;  
3 a second reactant disposed within a second sachet;  
4 a third sachet disposed about the first sachet and the second sachet;  
5 an envelope disposed about the third sachet;  
6 a frangible pouch disposed within the envelope adjacent to the third sachet; and  
7 an initiating agent disposed within the frangible pouch,  
8 wherein the first reactant and the second reactant generate a gas in the presence of the  
9 initiating agent, and the envelope allows release of the gas from the apparatus.

1 24. An apparatus for delivery of a gas comprising:  
2 a sachet;  
3 a partition disposed within the sachet defining a first volume and a second volume;  
4 a first reactant disposed in the first volume; and  
5 a second reactant disposed within the second volume,  
6 wherein the first reactant and the second reactant generate a gas in the presence of an  
7 initiating agent, and the sachet allows entry of the initiating agent into the apparatus.

1 25. The apparatus of claim 24 further comprising an envelope disposed about the  
2 sachet.

1 26. An apparatus for delivery of a gas comprising:  
2 a sachet; and  
3 a reactant disposed within the sachet that generates a gas in the presence of an initiating  
4 agent,  
5 wherein the sachet allows contact of the initiating agent with the reactant and release of the  
6 gas from the apparatus.

1 27. The apparatus of claim 26 wherein the sachet comprises a hydrophobic material  
2 having a pore size between about 0.01 $\mu$ m and about 50  $\mu$ m.

1 28. A method of forming an apparatus for delivery of a gas comprising:

- 53 -

2 (a) providing a multi-layer structure comprising a reactant layer centrally disposed  
3 between two sachet layers, and two envelope layers disposed adjacent to the two sachet layers  
4 such that the two sachet layers are centrally disposed between the two envelope layers; and

5 (b) stamping the multi-layer structure such that the two envelope layers form an envelope  
6 defined about its perimeter by the stamp, and the two sachet layers form a sachet defined about  
7 its perimeter by the stamp.

1 29. The method of claim 28 further comprising:

2 (c) providing a second two envelope layers and an initiating agent in a frangible pouch; and

3 (d) stamping the second two envelope layers to form a second envelope defined about its  
4 perimeter by the stamp, such that the frangible pouch and the envelope formed in step (b) are  
5 disposed within the second envelope.

1 30. A method of delivering gas comprising:

2 (a) providing an apparatus for delivery of a gas comprising:

3 an envelope,

4 a sachet disposed within the envelope, and

5 a reactant disposed within the sachet that generates a gas in the presence of an initiating  
6 agent,

7 wherein the envelope allows release of the gas from the envelope; and

8 (b) disposing the apparatus in an environment that comprises an initiating agent.

1 31. The method of claim 30 wherein the environment is liquid and the initiating agent  
2 is water.

1 32. The method of claim 30 wherein the environment is gaseous and the initiating  
2 agent is water vapor.

1 33. An apparatus for delivery of a gas comprising:

2 a barrier layer;

3 a sachet layer disposed adjacent to the barrier layer;

4 a reactant disposed between the barrier layer and the sachet layer that generates a gas in  
5 the presence of an initiating agent; and

6 an envelope layer disposed adjacent to the sachet layer,

- 54 -

7 wherein the envelope layer allows release of the gas from the apparatus.

1 34. The apparatus of claim 33 further comprising a desiccant disposed between the  
2 barrier layer and the sachet layer.

1 35. The apparatus of claim 33 wherein the sachet layer is a hydrophilic membrane.

1 36. The apparatus of claim 35 wherein the hydrophilic membrane sachet layer has a  
2 pore size of between about 0.01 microns and about 50 microns and a thickness between about  
3 100 microns and about 400 microns.

1 37. The apparatus of claim 33 wherein the envelope layer is a hydrophobic perforated  
2 film.

1 38. The apparatus of claim 37 wherein the envelope layer has a pore size of between  
2 about 0.05 microns and about 5 microns and a thickness between about 100 microns and about  
3 400 microns.

1 39. The apparatus of claim 33 further comprising a second barrier layer disposed  
2 adjacent to the envelope layer.

1 40. The apparatus of claim 33 wherein the barrier layer is formed to define a cavity  
2 and the reactant is disposed in the cavity.

1 41. The apparatus of claim 40 wherein the barrier layer further defines a second cavity  
2 and a desiccant disposed within the second cavity.

1 42. The apparatus of claim 33 further comprising a pouch having a spout and a cap,  
2 wherein the barrier layer is formed to attach to the cap.

1 43. The apparatus of claim 33 further comprising a spray bottle having a detachable  
2 portion, wherein the barrier layer is formed to attach to the detachable portion.

1 44. An apparatus for delivery of a gas comprising:  
2 a barrier layer formed to define a first cavity and a second cavity;

- 55 -

3 a sachet layer disposed adjacent to the barrier layer, the sachet layer comprising a  
4 hydrophilic membrane having a pore size of between about 0.05 microns and about 5 microns  
5 and a thickness between about 100 microns and 400 microns;

6 a reactant disposed between the barrier layer and the sachet layer in the first cavity that  
7 generates a gas in the presence of an initiating agent;

8 a desiccant disposed between the barrier layer and the sachet layer in the second cavity; and

9 an envelope layer disposed adjacent to the sachet layer, the sachet layer comprising a  
10 hydrophobic membrane having a pore size of between about 0.01 microns and 50 microns and a  
11 thickness between about 100 microns and 400 microns,

12 wherein the envelope layer allows release of the gas from the apparatus

1 45. An apparatus for delivery of a gas comprising:

2 a barrier layer;

3 a sachet layer disposed adjacent to the barrier layer; and

4 a reactant disposed between the barrier layer and the sachet layer that generates a gas in  
5 the presence of an initiating agent;

6 wherein the sachet layer allows entry of the initiating agent into the apparatus.

1 46. The apparatus of claim 45 wherein the sachet comprises a hydrophobic membrane  
2 having a pore size between about 0.01  $\mu\text{m}$  and about 50  $\mu\text{m}$ .

1 47. The apparatus of claim 45 wherein the barrier layer is formed to define a cavity  
2 and the reactant is disposed in the cavity.

1 48. The apparatus of claim 47 wherein the barrier layer further defines a second cavity  
2 and a desiccant disposed within the second cavity.

1 49. A method of forming an apparatus for delivery of a gas comprising:

2 (a) providing a multi-layer structure comprising a reactant layer centrally disposed between  
3 a sachet layer and a barrier layer, and an envelope layer disposed adjacent to the sachet layer; and

4 (b) sealing the perimeter of the barrier layer, sachet layer and barrier layer such that the  
5 reactant is disposed in a volume defined by the sachet layer and the barrier layer.

1 50. A method of forming an apparatus for delivery of a gas comprising:

- 56 -

2 (a) providing a multi-layer structure comprising a reactant layer centrally disposed between  
3 a sachet layer and a barrier layer; and

4 (b) sealing the multi-layer structure such that the such that the reactant is disposed in a  
5 volume defined by the sachet layer and the barrier layer.

1 51. A method of forming an apparatus for delivery of a gas comprising:

2 (a) providing an apparatus for delivery of a gas comprising an envelope layer, a sachet layer  
3 disposed adjacent to the envelope layer, a barrier layer disposed adjacent to the sachet layer, and  
4 a reactant disposed in a volume defined by the sachet layer and the barrier layer; and

5 (b) disposing the apparatus in an environment that comprises an initiating agent.

1 52. A method of delivering gas comprising:

2 (a) providing an apparatus for delivery of a gas comprising:

3 a barrier layer;

4 a sachet layer disposed adjacent to the barrier layer;

5 a reactant disposed between the barrier layer and the sachet layer that generates a  
6 gas in the presence of an initiating agent; and

7 an envelope layer disposed adjacent to the sachet layer,

8 wherein the envelope layer allows release of the gas from the apparatus; and

9 (b) disposing the apparatus in an environment that comprises an initiating agent.

1 53. The apparatus of claim 1 wherein the reactant comprises desiccant.

1 54. The apparatus of claim 1 wherein the sachet is disposed within a second sachet,  
2 and the second sachet is disposed within the envelope.

1 55. The apparatus of claim 54 wherein the second sachet is a selective transmission  
2 film.

1 56. The apparatus of claim 54 further comprising an initiating agent disposed within a  
2 frangible pouch, wherein the frangible pouch is disposed within the second sachet.

1 57. The apparatus of claim 54 further comprising an initiating agent disposed within a  
2 frangible pouch, wherein the frangible pouch is disposed within the envelope and outside the  
3 second sachet.

- 57 -

- 1 58. The apparatus of claim 25 wherein the envelope is a selective transmission film.

(54) Title: APPARATUS AND METHOD FOR CONTROLLED DELIVERY OF A GAS

(57) Abstract: Disclosed are apparatus (10) for delivery of a gas, e.g., carbon dioxide and/or chlorine dioxide, and methods of its use and manufacture. The apparatus (10) includes an envelope (20), and a sachet (30) within the envelope that contains reactant (40), which generates a gas in the presence of an initiating agent, e.g., water. In another embodiment, the apparatus includes a barrier layer, a sachet layer disposed adjacent to the barrier layer, a reactant disposed between the barrier layer and the sachet layer that generates a gas in the presence of an initiating agent, and an envelope layer disposed adjacent to the sachet layer.

## INTERNATIONAL SEARCH REPORT

International application No.  
PCT/US 01/05002

### Box I Observations where certain claims were found unsearchable (Continuation of Item 1 of first sheet)

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:  
because they relate to subject matter not required to be searched by this Authority, namely:
2. ☐ Claims Nos.:  
because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically:
3. ☐ Claims Nos.:  
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

### Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

see additional sheet

1. ☐ As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☒ No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

1-22, 26, 30-32, 53-58

Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest.
- ☐ No protest accompanied the payment of additional search fees.

FURTHER INFORMATION CONTINUED FROM PCT/ISA/ 210

This International Searching Authority found multiple (groups of) inventions in this international application, as follows:

1. Claims: 1-22,26,30-32, 53-58

An apparatus for delivering a gas comprising:

a sachet  
a reactant disposed within the sachet which generates a gas  
and possibly an envelope (claims 1-22,53-58) enclosing the sachet which allows release of the gas.

The corresponding method of delivering gas

2. Claims: 23-25

An apparatus for delivery of a gas comprising:  
a first reactant disposed within a first sachet  
a second reactant disposed within a second sachet  
a third sachet disposed about the first and second sachet  
an envelope disposed about the third sachet  
a frangible pouch disposed within the envelope adjacent to the first sachet and  
an initiating agent disposed within the frangible pouch  
and

An apparatus for delivery of a gas comprising:  
a sachet having a partition defining a first and a second volume  
a first reactant disposed in the first volume  
a second reactant disposed in the second volume

3. Claims: 28,29

A method for delivering a gas comprising:  
providing a multi-layer structure comprising a reactant layer centrally disposed between two sachet layers and two envelope layers  
stamping the multi-layer structure

4. Claims: 33-43,45-52

An apparatus for delivery of a gas comprising:  
a barrier layer  
a sachet layer disposed adjacent to the barrier layer  
a reactant disposed between the sachet layer and the barrier layer  
and possibly  
an envelope layer disposed adjacent to the sachet layer  
and the corresponding methods of forming the apparatus and

FURTHER INFORMATION CONTINUED FROM PCT/ISA/ 210

for delivering a gas.

5. Claim : 44

An apparatus for delivery of a gas comprising:  
a barrier layer formed to define a first cavity and a second cavity  
a sachet layer disposed adjacent to the barrier layer  
a reactant disposed between the barrier layer and the sachet layer in the first cavity  
a dessicant disposed between the barrier layer and the sachet layer in the second cavity  
an envelope layer disposed adjacent to the sachet layer.
